

This is a digital copy of a book that was preserved for generations on library shelves before it was carefully scanned by Google as part of a project to make the world's books discoverable online.

It has survived long enough for the copyright to expire and the book to enter the public domain. A public domain book is one that was never subject to copyright or whose legal copyright term has expired. Whether a book is in the public domain may vary country to country. Public domain books are our gateways to the past, representing a wealth of history, culture and knowledge that's often difficult to discover.

Marks, notations and other marginalia present in the original volume will appear in this file - a reminder of this book's long journey from the publisher to a library and finally to you.

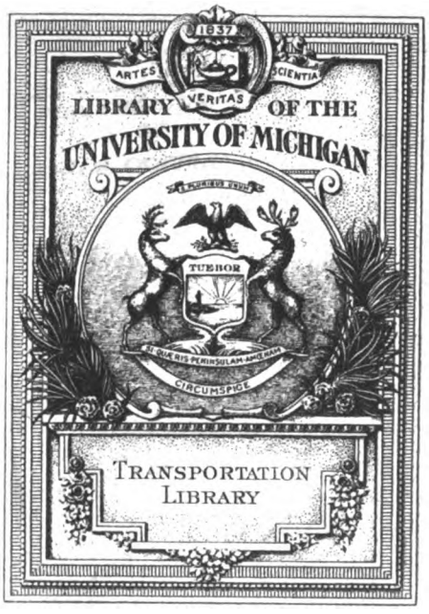
Usage guidelines

Google is proud to partner with libraries to digitize public domain materials and make them widely accessible. Public domain books belong to the public and we are merely their custodians. Nevertheless, this work is expensive, so in order to keep providing this resource, we have taken steps to prevent abuse by commercial parties, including placing technical restrictions on automated querying.

We also ask that you:

+ *Make non-commercial use of the files* We designed Google Book Search for use by individuals, and we request that you use these files for personal, non-commercial purposes.

+ *Refrain from automated querying* Do not send automated queries of any sort to Google's system: If you are conducting research on machine translation, optical character recognition or other areas where access to a large amount of text is helpful, please contact us. We encourage the use of public domain materials for these purposes and may be able to help.



+ *Maintain attribution* The Google "watermark" you see on each file is essential for informing people about this project and helping them find additional materials through Google Book Search. Please do not remove it.

+ *Keep it legal* Whatever your use, remember that you are responsible for ensuring that what you are doing is legal. Do not assume that just because we believe a book is in the public domain for users in the United States, that the work is also in the public domain for users in other countries. Whether a book is still in copyright varies from country to country, and we can't offer guidance on whether any specific use of any specific book is allowed. Please do not assume that a book's appearance in Google Book Search means it can be used in any manner anywhere in the world. Copyright infringement liability can be quite severe.

About Google Book Search

Google's mission is to organize the world's information and to make it universally accessible and useful. Google Book Search helps readers discover the world's books while helping authors and publishers reach new audiences. You can search through the full text of this book on the web at `http://books.google.com/`

THE WINNING CAR

in most really notable automobile events, is equipped with Hartford Tires.

¶ This is a fact that should be most significant to the man who buys tires.

¶ It proves that the men who really know, and who have learned, perhaps by bitter defeat and disappointment, that the best, and the best only, is real economy, recognize in Hartford Tires the highest standard of quality.

¶ The Philadelphia North American, of June 14, speaking editorially of the winning car at Point Breeze track, June 13th, says: "Tire trouble of the slightest kind would have meant defeat, but the Hartford Tires on the machine did their work nobly."

¶ And so the story goes—ever and always success on Hartford Tires. Get them on YOUR car.

Hartford Tires

"The tire with the doubt and the risk left out"

are always the same in quality. All one grade—the best, and the trade marks here reproduced are your guarantee and protection.

Hartford Tires and Hartford Tubes

the world's best for quality, resiliency, durability and satisfaction.

FRANKLIN Automobiles

Excessive weight cannot make an automobile strong nor safe. But it makes big bills.

The Franklin Model "H" touring-car is unique among automobiles. It weighs less than 2,600 pounds. It has 42 horse-power. Its engine is a six-cylinder. It carries seven passengers comfortably. Yet it is lighter than any standard five-passenger, water-cooled automobile.

Consider what that means in net power, and ability on American roads. Consider the economy.

Type "H" is faster than any touring-car of anywhere near its power. It has large wheels and tires; and like all Franklins, it has full elliptic spring suspension and laminated wood frame—making its riding qualities comfortable and easeful beyond comparison. No shock to the passengers; no racking of the machine. And you can steer it with one hand.

A heavy automobile pounds heavily on the road—that means rapid wear-and-tear and discomfort. It is harder to control—that means danger. And the running-cost and depreciation-cost are unreasonable.

The Franklin air-cooled engine not only gets rid of weight, but of trouble and complication. It economizes fuel wonderfully; and it cools perfectly, even running idle—a thing no water-cooled motor will do.

Type "H" is the handsomest touring-car on the market. Its body of sheet metal is a work of art. No Franklin has the cheap wood body nor the heavy cast body. And you never knew a Franklin to wear out.

Before you buy any automobile see it weighed and test its strength.

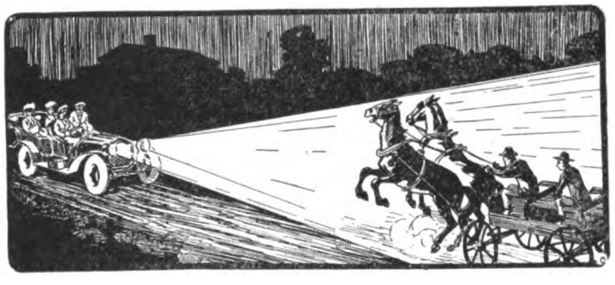
The Auto-Meter—Is Believed

Every big motor event that has taken place in the past three or four years has seen more Auto-Meters in evidence than all other makes of speed indicators combined.

In the Glidden Tours the number of Auto-Meters used by contestants doubled and tripled all other makes put together.

In the New York-Paris Race the only speed indicator is a Warner on the Thomas car.

Nearly all the automobile manufacturers of the country use the Warner to test out their cars before they leave the factory.



Two of the most successful makers are including the Warner as part of their regular equipment.

Aren't these facts rather significant—don't they mean anything to you?

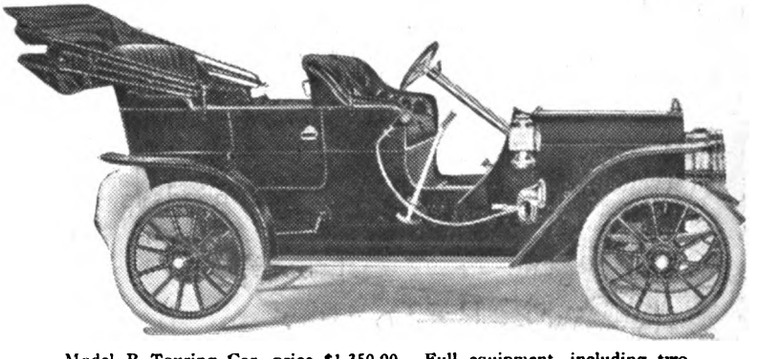
Send for our new book, "The Final Truth About Speed Indicators."

Warner Instrument Co.

210 Wheeler Ave., Beloit, Wis.

AVOID ACCIDENTS

by using the



Wridgway No Glare Shade

which adds to the efficiency of the lamps, and keeps glare from blinding other users of the highways. Can be fitted to any existing lamp.

Large Sales

make it possible for us to import **THE CELEBRATED BRAMPTON CHAINS** from **ENGLAND** (paying freight and duty), and sell them at the same price at which the several other automobile chains are sold to manufacturers, jobbers, dealers and users.

THE BRAMPTON MOTOR CHAIN

All side plates on both sides on the Brampton Chain are stamped **"BRAMPTON."**

LARGE SALES and SMALL PROFIT with thousands of satisfied customers is our best advertisement.

THE BRAMPTON CHAIN is made of helf-hardening Steel; the strongest Chain in the World. All parts polished; fits sprockets (that are properly cut) without friction.

Some of the other chains may look like **THE CELEBRATED BRAMPTON CHAIN** because some of the other chain makers began to copy the design and shape of the **BRAMPTON CHAIN** links in 1904. They have improved somewhat on their copied design from time to time until these chains now look more like the **BRAMPTON CHAIN** than ever before. These chains somewhat resemble the **BRAMPTON** in appearance, but the manufacturers of such chains have been unable to copy the material—self-hardening steel.

NO CHANGE IN THE BRAMPTON

There has been no change in the design, construction, material or finish of the **BRAMPTON MOTOR CHAIN** in the past ten years.—**"ENUF SED."**

PRICE

The price being equal, it's presumable you want the best, and full value for your money. In such cases, the **BRAMPTON FILLS THE BILL**, and the prices are the same to manufacturers, jobbers, dealers and consumers as any other chain of equal size—as follows:

CHAINS TO FIT AMERICAN CARS

1 x ⅜ x 9-16—1 x ½ x ⅝—1 x ½ x 9-16 roller	$1.00 per foot.
1 x ⅝ x ⅝ roller	1.17 "
1¼ x ½ x ⅝—1¼ x ⅝ x ⅝—1¼ x ⅝ x ¾ roller	1.25 "

We also carry in stock the **BRAMPTON CHAINS** to fit Foreign Cars—Mercedes, Panhard, Martini, Fiat, etc.

Your 1908 Car

You can have the new car that you order fitted with the **CELEBRATED BRAMPTON CHAIN** if you order it that way. No extra cost to either you or the manufacturer. All standard sizes in stock to fit American and Foreign Cars at the same price as the other chains.

SPECIAL CHAINS TO FIT THE INDIAN MOTORCYCLE.

Agents wanted in unoccupied territory. Catalog on request.

We are Sole American Agents for **BRAMPTON CHAINS**, and they cannot be bought from anyone else except through our Agents.

Pan-American Automobile Body Polish

Pan-American Polish was awarded the Bronze Medal at the Louisiana Purchase Exposition at St. Louis, 1904. This polish has been carefully prepared for the Automobile trade. It is also applicable to the carriage trade, or can be used on any varnished furniture or woodwork of any kind. It will remove stains, cover scratches; leaves the automobile with its original new lustre, without being sticky or greasy. Furnished in eight-ounce bottles. Guaranteed not to harm the finest varnish. For sale by all Automobile Dealers. **Price 60 cents per bottle.**

The Miller Automobile Jack

The Miller Automobile Jack is a quick acting, automatic lowering jack, designed especially for automobile use, and is adapted to the factory or garage as well as to be carried as a part of the equipment on motor cars. It is high-grade and one of the finest finished jacks on the market. We guarantee this jack for twelve months. The list price of the Miller Jack, **$3.50 each.**

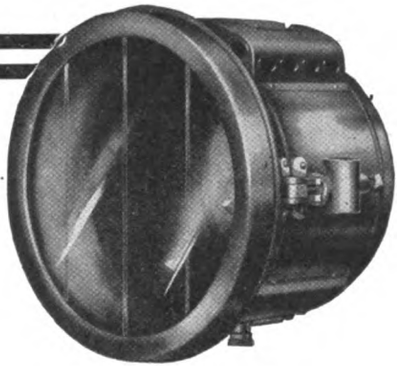
If you want good tire service and are not getting it; or,

If you believe it possible to reduce your present yearly tire bill—

a comparative test of



MORGAN & WRIGHT TIRES

on the same car with other brands, will satisfy you that such a result can be had—and without any extra cost over the price you pay for other tires.

YOU CAN'T DO A BETTER THING THAN TO "TRY THEM OUT"

MORGAN & WRIGHT, Detroit

Branches, Agencies or Dealers Everywhere

To Sum Up—

Solar Motor Lamps are superior to those of other manufacture for the following reasons:

(1) The internal method of screw assembling insures a perfectly smooth exterior. (2) All parts are interchangeable. (3) They have fewer parts. (4) Are more simple in construction. (5) Less solder is used. (6) The brass has more "body"—they are heavier and more durable. (7) They are better in design. (8) Special B & L Solar short focus Mangin Mirrors are used and each lamp is tested for accuracy of focus. The highest efficiency as regards lighting is assured.

No detail is overlooked in the construction of Solar Lamps. The Solar Nameplate is a positive guarantee to the user that he has the best in lighting equipment.

The "Maxwell"

THE RUMOR SEASON

is here again, just as it always comes with the regularity of the malaria germ, or the hay-fever, or the June-bug; only it becomes more virulent as it gets older.

The Whooper Company—so Dame Rumor says—will have a world-beater in the shape of a motor that has more cycles to it than you have fingers and toes, to sell at —$. Just wait and see.

The Spouter Company has something up its sleeve that will be a combination of features as variegated as the ingredients in a mince pie, to sell at — $. They will show you later.

The Holler Company has a new startler of the wait-till-we-show-you-and-get-left kind, a conglomeration of metals so diversified as to make the most enterprising experimenter in the mixer of metals quit his job in disgust, and it will sell at — $. A lick and a promise.

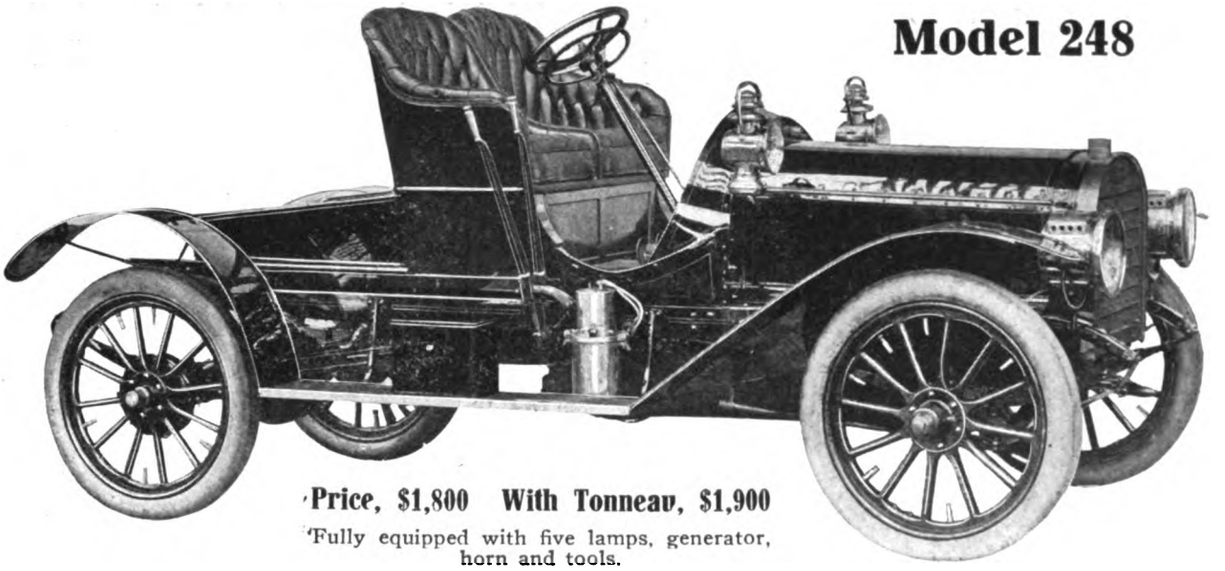
And so it goes on—if you have been in the business long enough you will know the story.

Not so facetious, but similar in trend, are the reflections as one scans the horizon of trade promises. I have been asked what we are going to do, and when I started to write this ad it was to give the answer:

We have found that with Maxwell principles of automobile construction and with honest manufacture and decent selling methods old terra firma is a good enough place to do business on and we are going to stay on earth, saving ourselves the trouble to come down again after the soaring flights of fancy in which some of our friends now indulge.

We are in the automobile business for the profits that are in it, and we are satisfied with the results. It pays to build the only good moderate priced automobile. Our dealers are satisfied, for they, too, find legitimate effort rewarded with a legitimate profit. Maxwell owners are satisfied, because they know that they possess a car that will give satisfactory service at minimum expense, every day in the year, and that looks as stylish and imposing—without extra charge for the style and imposition—as the highest-priced cars made anywhere. Being built upon well-tried design and honestly made they are free from the find-me-out-later-on handicap of some other manufacturers.

We will sell Maxwell cars, some ten thousand of them, at legitimate prices—prices high enough to give to our dealers and to ourselves a legitimate profit and low enough to give to every purchaser the full value of his money.



The only change we will make will be in the distribution of profits resulting from the sale of Maxwell cars. Here the new arrangement will favor the individual dealer, giving the hustler the hustler's reward. If you are a hustler we want you and you will want us So let's get together as soon as possible. Write to me now, telling me something of your territory and its sales possibilities, and I will communicate with you and tell you of the new Maxwell selling plan, the plan for business-getters.

Benj Briscoe
President.

THE MOTOR WORLD

Volume XVIII. New York, U. S. A., Thursday, Thursday, July 2, 1908. No. 14

MAKERS OF SPEEDOMETERS CONFER

Problem of Regulating Prices the Subject of Discussion—No Action Taken, but Another Meeting is Probable.

Following the successive conferences of first the tire manufacturers and next the lamp makers, a meeting of those manufacturers of speedometers who are members of the Motor and Accessory Manufacturers, Inc., was called by D. J. Post at the Hotel Belmont, New York, on Monday of this week.

Its purpose, like those of the two meetings which preceeded it, was to try to devise ways and means for the proper regulation of prices and their maintenance, and the correction of such abuses and shortcomings as have gradually developed.

Representatives of three concerns were present and while it was admitted that some dealers were guilty, it was conceded that the jobbers were the worst offenders, and their regulation a difficult matter unless by the drastic method of elimination. As is generally known, one prominent maker has already practically done this very thing. He has secured proof of violation of price contracts and has gone even further by searching out reputed offenders, and where proof is secured inflicting the penalty of cutting them off the list. This position, he announced, will be maintained, and while its logic is admitted, its expediency is questioned unless all the makers are brought into line and agree to act in unison and in good faith.

It is likely that a further meeting will be called at which some definite plan will be submitted for action.

Crown Battery Seeks Dissolution.

Judge Blanchard of the New York Supreme Court has appointed Jacob J. Long, receiver of the Crown Battery Co., 192 Southern Boulevard, New York City. Mr. Long with John R. Pettit, both directors of the company, petitioned for its voluntary dissolution. The company's liabilities aggregate $6,855; the assets comprise cash, $4; accounts, $904; plant and machinery, value not stated. The Crown Battery Co. was incorporated March 1, 1907, with a capital stock of $20,000, increase to $50,000 on February 1, 1908, and was engaged in the manufacture of dry cells and electric batteries.

Payment of Pope Dividend Ordered.

Vice Chancellor Howell of the New Jersey chancery court has signed an order directing the receivers of the Pope Mfg. Co. to pay a 25 per cent. dividend on all approved claims against the company. The dividend was conditionally authorized several weeks ago to take place as soon as the $50,000 was received from the sale of stock of the American Wood Rim Co., owned by the Pope company and which was sold to E. J. Lobdell, the head of the wood rim pool.

The order also directs the receivers to set aside $65,000 for the future payment of 25 per cent. on the claim of Louise A., Josephine, Anna L. and Otto F. Unzicker, who are owners of premises formerly occupied by the Western Wheel Works, in Chicago, which had been leased by the Pope company, which lease at $25,000 per year, has 17 years to run. The receivers are further ordered to deduct from the dividend due the International Trust Co. of Boston the amount of money on deposit with it to the credit of the Pope company at the time of the appointment of the receivers.

In accordance with the order, checks were mailed to the creditors this week. It is expected that a second dividend of 25 per cent., if not more, shortly will be declared.

Standard Rim Bobs Up Again.

A meeting of the committee on the standardization of rims was held on Monday of this week, and declared for a continuation of the present policy—whatever that may be. A standard rim is likely to be adopted just as soon as it is decided which rim is best.

SPEEDOMETER COMPANY ASSIGNS

Trustees Appointed for the R. H. Smith Mfg. Co., of Springfield—The Step Taken for Protection of Creditors.

Following only a short time after the nominal reorganization which was occasioned by the shocking death of R. Hale Smith, its former president, the R. H. Smith Mfg. Co., Springfield, Mass., assigned to Robert A. Knight and Charles H. Beckwith, trustees, late last week. The action was taken on behalf of and by the consent of creditors representing a large part of the company's liabilities, which are said to total approximately $50,000, and was purely a protective measure.

Both the rubber stamp and speedometer business, which represents the company's invested capital, are in profitable condition, Attorney Knight declared in a recent interview, and for that reason, there is likely to be no change in the conduct of the business. The main reason for the assignment, he said, was simply that the business had outgrown its capital. The company is capitalized at $20,000. Notice of the assignment was issued to the creditors in the form of the following communication under date of Friday, 26th ult.:

"The R. H. Smith Manufacturing Co. of this city, deeming it advisable for the protection of its creditors, has this day made an assignment to the undersigned for the benefit of its creditors. An inventory is being taken, which will soon be completed, and you will then receive from us a copy of the same, with a copy of the instrument of assignment and further information regarding the condition of the company.

"Respectfully yours,

(Signed)

"ROBERT A. KNIGHT,

"CHARLES H. BECKWITH,

"Trustees."

Just what definite course will be pursued to take care of the company's liabilities is uncertain, according to Attorney Knight. He said the company had about

Digitized by Google

3,000 of the Smith speedometers in stock, and steps would be taken immediately to convert some of the company's assets into cash.

It was said that the rubber stamp business had been unusually successful over a period of 25 years, and has in that time contributed handsome profits to the company. The speedometer, which was taken on by the company about three years ago, is regarded to-day a mechanical success.

Through the three years that the speedometer business has been carried by the company, however, the progress on the invention has been largely experimental, a process which has been costly and has consumed the company's surplus. To-day, when the business is actually on a paying basis, it is asserted, the interests of the company's creditors as a whole demand that the business be safeguarded in order to prevent a smash.

Fiat Absorbs Palais de l'Automobile.

By a deal effected on Saturday, 27th ult., the Fiat Automobile Co., of New York City, becomes exclusive American distributors of Delaunay-Belleville cars and subagents for Renault and Panhard cars. On that date the company officially absorbed the Palais de l'Automobile, having previously effected a union with the Auto Import Co., sole American agents of Rochet-Schneider cars. H. Nepbauer, former manager of the Palais de lAutomobile, becomes second vice-president of the Fiat Automobile Co., and on July 1 will take up his office in the new headquarters of the latter at No. 1786 Broadway. E. Rand Hollander remains first vice-president and general manager of the enlarged company.

The cause of the absorption, first of the Auto Import Co. and then of the Palais de l'Automobile, is declared to be directly due to the lowering of Fiat prices to an American basis. The sales of Rochet-Schneider and Delaunay-Belleville cars were considerably affected and unable to meet the Fiat prices. Negotiationswere opened in behalf of both of these makes that have ended in the consolidation of all three. While Fiat cars will constitute the principal output of the company, users of the other makes will be looked after.

Changes in the Winton Staff.

Following the promotion of Charles W. Churchill, formerly New York branch manager, to the general sales management the Winton Motor Carriage Co., announces other changes in the staff. Charles M. Brown, San Francisco branch manager and formerly manager of the Winton branch in Chicago, has been named to take the management of the New York branch. Harry L. Owesney, assistant manager of the San Francisco branch, becomes manager of that branch. The company also announces that W. L. Duck, former London branch manager, will be manager of the Baltimore branch, vice R. H. Williams, resigned.

The Week's Incorporations

Long Beach, Cal.—Electric Automobile Co. of Long Beach, under California laws, with $10,000 capital.

Dover, Del.—Guaranteed Faultless Auto Tube Co., under Delaware laws, with $1,000,000 capital. Corporators—F. N. Hipple, J. W. Ebbs, M. L. Ward, New York City, N. Y.

Chicago, Ill.—North Automobile Co., under Illinois laws, with $2,500 capital; general manufacturing and merchandise business. Corporators—A. B. Pease, L. Pierson, George A. Miller.

Jersey City, N. J.—Elkwood Park Automobile Association, under New Jersey laws, with $10,000 capital; to hold and manage automobile races, exhibitions, shows, etc. Corporators—B. S. Mantz, J. R. Turner, R. R. Thien.

New York City, N. Y.—S. P. O. Automobile Co., under New York laws, with $25,000 capital. Corporators—Jules Godefroy, 316 West Twenty-fifth street; Albert M. Newburgh, 150 Nassau street; Anna H. Peyser, 245 West 111th street, New York City, N. Y.

Camden, N. J.—Grant-Hoover Ball Co., under New Jersey laws, with $200,000 capital; to manufacture ball and roller bearings for axles of trucks, railroad cars, wagons, carriages, etc. Corporators—R. H. Grant, L. J. Hoover, V. E. Frank, Camden, N. J.

New York City, N. Y.—Central Park Taxicar Co., under New York laws, with $10,000 capital. Corporators—Henry Schultz, 1864 Seventh avenue; George Hahn, 160 East Ninety-fifth street, New York City N. Y.; C. Bertram Plante, 763 Eastern Parkway, Brooklyn, N. Y.

In the Retail World.

The Ellicott Motor Car Co., Buffalo, N. Y., has been discharged in bankruptcy.

W. R. Barger has arranged to open an exclusive Cadillac agency in Cleveland, O., on Euclid avenue, just east of the Hartford Rubber Co.'s local branch.

Thomas G. Miller and Charles F. Holden have opened a new garage in Colorado Springs, Col., at the north end. They have secured the agency for the Gearless car. Their garage is at 1206 North Cascade avenue.

The Lakeside Automobile Co., of St. Louis, has reorganized as the Swingley Motor Car Co. J. A. Prescott continues in the position of manager. The company handles the Car de Luxe, Jackson and Stoddard-Dayton.

Vice-Chancellor Howell at Newark on the 24th ult., appointed William H. Brown receiver of the Hygrade Motor Co., 9 Hill street, Newark. Insolvency is alleged in a bill filed for J. Harry Hardman, the petitioning creditor.

T. Browning Spence has bought a majority of shares in the Pope Automobile Co., Washington, D. C., and will be elected president of the company. C. Royce Hough, who has been manager since 1899, will be retained in that position.

Among losers by a fire in the building 1525-1531 Maryland avenue, Baltimore, on the 25th ult., was the Maryland Auto Tire Repair Works. The building was so badly damaged that it has been condemned and all the occupants have been ordered to vacate.

W. Wayne Davis is manager of the new Matheson branch in Philadelphia, which was opened on the 29th ult. It is located at Broad and Green streets. Mr. Davis is chairman of the automobile committee for "Founders' Week," when the Quaker City will celebrate its 225th anniversary. The appointment was made by the mayor.

On July 1 of this week, the Harry Fosdick Co., long identified with the automobile interests of Boston, Mass., retired from business. The lease of their store in the Motor Mart has been taken up by the Buick Motor Co., which established a Boston branch at that place on the date named.

Otto Braunworth, proprietor of the Broadway Rubber Tire Works, Manhattan, has opened an automobile supply store at 53 West Fifty-third street. He will conduct it in conjunction with his tire repairing plant next door. Hereafter his business will be conducted under the name of the Broadway Auto Accessory Co.

The Augusta Motor Co. is the designation of a branch house to be established in Augusta, Ga., by the Charleston Motor Co., of Charleston, S. C. L. M. Coward is making the local arrangements and has secured a location at 712 Ellis street. The company will conduct an agency for five different manufacturers.

C. A. Coey & Co., Chicago, filed four "automobile debt" suits in the municipal court on the 26th ult., one of which may interfere with the debtor's intended trip to Europe. In this case the Coey Automobile Livery Co., also has a suit, the claim being for a storage bill amounting to $1,000. Conrad Seipp, Jr., is the defendant, and the bill of C. A. Coey & Co. is for an alleged balance of $2,000 on a new machine. Another of the suits is against M. B. Hereley, traction expert for the city, from whom the firm wants to collect $5.000, alleged to be due for a new car. The Coey Automobile Livery Co. adds another suit to the four of the Coey firm, making five in all.

Cadillac to Open a New York Branch.

The Cadillac Motor Car Co., of Detroit, Mich., has decided to open a New York branch, from whence all their eastern business will be handled. Temporary quarters have been taken at Broadway and Fifty-first street, and early in the Fall they expect to occupy a new building now in course of erection. Ernest H. Brandt will be in charge.

TARIFF BARS AMERICAN TIRES

Discriminative Duties Practically Close the French Market—One American Type Manufactured in France.

Although rubber tires are not listed separately in the statistics of American exports, it is generally known that the foreign market has not been extensively cultivated by the American tire makers. A valid excuse for this state of affairs, at least as existing in France, is furnished by Consul-General Robert P. Skinner, of Marseilles, who points to the duty wall which blocks the way, and which amounts to practically 8 cents per pound, as against 6 cents a pound levied against tires imported from other countries.

"A very serious obstacle to the creation of a demand in France for rubber tires of American manufacture is the application of a duty upon such tires of 90 francs per 100 kilos ($17.37 per 220 pounds)," says Consul-General Skinner. "The consequence is that importations from the United States have been unimportant. It is impossible to furnish any reliable statistics regarding the trade, as rubber tires are comprised with a long list of other articles in rubber.

"One well known American house, appreciative of the difficulties of disposing of American tires in France, has passed over to a French firm its patent rights, with the result that, as in several other lines of industry, 'American' solid rubber tires are being very extensively sold in this country, although there is nothing American about them except the type.

"The general demand is said to be for a solid tire through which run two parallel steel wires. A pair of tires for wheels 39.37 inches in circumference commands from $24.30 to $35.90, according to the thickness of the round rubber, and flat tires for wheels of the same size run up to $96.50.

"Very few imported automobile tires are sold in this market for the same reasons as in the preceding case. Prices are steadily descending, in sympathy with the cost of raw rubber. It is said that $160,000 worth of these tires were sold last year in this city. The tires offered for sale are being improved annually, not in respect to the rubber portions, but as regards the canvas linings.

"It is calculated that a smooth-surface tire should run between 5,000 and 6,000 kilometers (3,106 and 3,728 miles), while the anti-skidding tires are hardly good for more than 4,000 kilometers (2,485 miles) on French roads. It is comparatively seldom that one sees a general service automobile in cities without at least one nail-shod tire. There is quite a variety of these devices, some being nail-shod leather envelopes, others metal nails on the rubber envelopes, and still others rubber nails which are a part of the rubber envelope itself. Eventually the nail wears through the canvas linings, and then repairs are difficult. The use of chains woven about smooth tires, such as are seen in New York, would not be permitted here under any circumstances. As it is the nailed tires are doing incalculable damage to the roads."

How Consular Advices Benefit Trade.

Interesting as showing the beneficial results obtainable by following up advices received from the American Cansular Service, is the result of one such hint which recently reached the officers of an association of automobile manufacturers. Consul Miller, of Matamoros, advised them that there was not a single automobile in that Mexican district. Acting on the suggestion, numerous catalogues were sent out by the members of the association, in consequence of which, at least two sales are in immediate prospect, while in a third case, the establishment of a 25 mile motor 'bus line from Matamoros to the seashore is contemplated. As there is no railroad transportation in the immediate vicinity of the proposed route, the scheme is very favorably regarded. The trial equipment, it is said, is to be rented at Brownsville, Tex., pending developments which will warrent a more extensive outlay of capital.

Kansas City Developing a Motor Buggy.

Although formerly devoted exclusively to the production of commercial vehicles, the plant of the Kansas City (Mo.) Motor Car Co., at Sheffield, is at present occupied with the development of a motor buggy, which is being built under the direction of A. R. Walton, formerly with the Dorris Motor Car Co., of St. Louis. It is intimated that a "deal" is in prospect whereby a local implement firm will take over a certain number of the cars provided they work out in a satisfactory manner. A reorganization of the company, which has been in financial difficulties for some little time, is said to be among the early prospects.

Reeves on the Road to Recovery.

The many friends of Alfred Reeves, general manager of the American Motor Car Manufacturers' Association, who was operated on for appendicitis on the 24th ult., at St. John's Hospital in Yonkers, N. Y., will be glad to learn that he has passed the critical stage of his illness and is convalescing rapidly. He expects to be able to resume his regular work about the middle of the month.

Makes a Second Offer for Pope Claims.

The Chicago concern which makes a business of doing such things, has offered creditors of the Pope Mfg. Co. 85 per cent. of the face value of their claims. About a month ago, it made a similar offer of 75 per cent.

CUSHION SPRINGS IN LITIGATION

Infringement of the Stotts Patent Alleged Against a Kalamazoo Manufacturer—Three Corporations Involved.

Springs of the type commonly employed in automobile upholstery and embodying the auxiliary or supplementary spring feature, are furnishing subject matter for litigation in the United States Circuit Court for the Western District of Michigan, in which Rummler & Rummler, patent attorneys for the Ventilated Cushion & Spring Co., of Jackson, Mich., have brought suit against Frank P. D'Arcy, of Kalamazoo, Mich., for infringement of what is known as the Stotts patent. The proceedings are based upon the production by D'Arcy of a spring construction which has been advertised and described as the product of the D'Arcy Spring Co., of Kalamazoo. This device, it is alleged, constitutes an infringement of five different claims of the Stotts patent.

The construction of the D'Arcy spring differs from that employed by the Ventilated Cushion Co., in that it omits the connection between the upper ends of the short or auxiliary springs, and also in that it has the short springs so set into the bottom frame as to permit of a slight lateral shifting. Otherwise, it is said to be similar in principle.

The Stotts patent for "Spring Structure," was issued on January 8, 1907, and assigned to the Ventilated Cushion & Spring Co., a month later. It is one of a group of patents owned by the company and reinforced by applications for others, bearing on the same subject and completely covering spring structures with auxilliary or supplementary springs, as is claimed.

The action, though taken by the Ventilated Cushion Co., also covers the rights of the Jackson Cushion Spring Co., of Jackson, Mich., licensees of the former concern, who are thereby afforded protection against the manufacture, sale and use of infringing spring constructions.

Boston Gets Taximeter Cab Service.

Fifty Thomas motor cabs were put into taximeter service in Boston, Mass., last week by the Taxi Motor Cab Co., under the direction of William P. Barnhart. The company's headquarters are located in the Park SquareMotor Mart, and substations are to be established at all leading hotels, clubs, cafes, and at both railroad stations. The usual tariff of 30 cents for the first half mile, and 10 cents for each succeeding half mile, or each six minutes waiting, will be charged. The plans for this first introduction of the taximeter vehicle into the Hub call for an ultimate equipment of 150 vehicles, to be installed as soon as conditions warrant.

WHITE WINS

A Partial Summary of Victories, May, 1907-May, 1908

Perfect Score in Harrisburg Endurance Run

Tieing with three other cars in the contest of May 5th-6th, 1907. For the result of the "run-off," see below.

Fastest Time in Wilkes-Barre Hill-Climb

Defeating 45 high-powered gasolene cars, in the great contest on Decoration Day, 1907.

Fastest Time in Cleveland Hill-Climb

Defeating 40 high-powered gasoline cars.

Fastest Time in California Hill-Climb

Defeating the fastest of its gasoline competitors by nearly two minutes on the 2⅞ mile hill at Witter.

Perfect Scores in Sealed Bonnet Contest

Both White cars entered made perfect scores in this contest conducted by the Automobile Club of America.

Officially Observed Non-stop Run of 1871 Miles

Held under the auspices of the Royal Automobile Club of England and certified by that organization.

Fastest Time of the Season on the Track

One mile in 1:02, ten miles in 12:54, and twenty-five miles in 29:07 at the Santa Rosa Track Meet.

Officially Declared Most Efficient Car

In the South Harting hill-climb, conducted by the Royal Automobile Club, the White won the contest because it developed at the rear wheels a greater percentage of its assigned horsepower than did any other car. The rating assigned to the White was 50 horsepower.

Wins English Dust Trials

Proving officially that it raises less dust than any other car.

Clean Sweep in the Glidden Tour

Three White entries make three perfect scores.

Won Hower Trophy

The single White runabout entered in the Glidden Tour defeated a dozen high-priced gasoline runabouts competing for this prize.

Won California Reliability Contest

In the original contest held September 20th, two Whites tied with two gasoline cars. In the "run-off" held November 15th and 16th, both Whites made perfect scores, while both gasoline cars were penalized.

Won Quaker City Endurance Run

In this contest, held January 1st, 2d and 5th, the White vanquished 27 gasoline cars of 23 leading makes, winning the MacDonald & Campbell trophy.

Fastest Time in San Francisco Hill-Climb

Winning the free-for-all, the $2,500 class and the $3,500 class.

Fastest Time in the New York Carnival Hill-Climb

Making the ascent of Fort George hill in 32⅕ seconds, compared with the best gasoline time of 36 seconds; largest entry list of any hill-climb ever held.

New San Francisco-Los Angeles Record

The White car made the 478-mile mountainous journey in 17 hours and 17 minutes, cutting 56 minutes from the previous figures.

Double Victory in Harrisburg Endurance Run

The single White entry was the only touring car to make a perfect score, winning the principal 1908 trophy, the Board of Trade Cup, and also the 1907 prize in a "run-off" with last year's other perfect-score drivers.

Perfect Score in Detroit Endurance Run

Perfect Score in Baltimore Sealed Mechanism Contest

Two Perfect Scores in Kansas City Reliability Run

Elimination of the "Season Feature."

A striking feature of the present season is the great number of new models which are being brought out—whether in anticipation of the market of 1909, or as timely additions to the present listings, does not matter in this connection. The fact that practically all of these machines are designed with a direct view to general utility, whether in veritable commercial operation, or as pleasure cars for all around service, also need not be considered; nor the fact that a very great proportion of them are of the so-called popular type. The very essential point in connection with the frequent use of the numerals 1909, is that when the new calendar shall have arrived, it will find a great majority of the makers prepared for the season, and it will unfold a market in which will be listed for the most part, only cars which have been tried out and refined to the complete satisfaction of the makers.

This elimination of the "season feature" in the industry, which has been practically assured for some little time, also has an important bearing on the display of machines at the shows. It means, in the first place, that the old, familiar and nerve-racking rush to get ready the various exhibits for the show will soon become a thing of the past. Changes in the market will come more slowly than heretofore, and the makers will no longer strive to have an entire new line for every exhibition of national importance which is held. The dubious proof of undue haste, which has been so marked hitherto, when cars frequently were shown incomplete, or were finished after being placed in position, will be visible no longer, and the show will become an exposition of what exists, rather than of what is planned for the future, more or less contingent on the results of the show itself.

If one great fault existed in nearly all shows of the past it was that their exhibits, many of them, were of too visionary a nature to be satisfactory to the careful buyer. The invariable consequence was that the actual results of show campaigns, did not appear until long afterward, when the cars themselves were actually ready for delivery, while many of the sales booked at the shows, did not materialize as expected. With the new order of things, this will be changed. Buyers will be able to examine a finished and satisfactory product under the most favorable of conditions, while the makers will be saved a vast deal of overtime rush work in preparation for them, and will have the confidence bred of handling a known product, in presenting their wares.

Evils of Overstating the Output.

One of the most insidious evils to which the automobile industry has fallen heir is the tendency to the circulation of stories of huge outputs, such as are wont to make their appearance from time to time. Superficially it might appear that these rumors —many of them are hardly more—could have no effect other than to attract attention to the particular makes of car with which the inflated figures happen to be associated. Actually, the result is far more searching and reaches to the very heart of the industry, while the public, upon which the effect would be supposed to fall directly, suffers only in a secondary and rather roundabout way.

To the prospective buyer, stories of the immense production, of one or another of the makers acts primarily as a stimulant to investigation. A natural conclusion which in many cases follows immediately afterward, is that at the visible rate of present consumption, this great number of machines cannot be disposed of at present prices. The result is a strong temptation to wait for a cut in prices. This temptation is increased by the inbred conviction in the breast of the average man outside the confines of the industry, that sooner or later an era of automobile bargains will arrive—just how, does not matter.

But even more disastrous than the delaying of a few orders from individual owners, is the corresponding effect upon the agents. In this case, however, the effect is emphasized by a close comparison of the figures of other maker's outputs, garnered from the press, and from the channels of trade gossip. Where it is commonly believed that a maker's output is exceeding the probable demand for his product, the shrewd dealer inclines, like the shrewd customer, to wait for bargain day. Where, on the other hand, rumor and gossip concur in rating a maker as successful on a large scale, the tendency is for the agent to overrate his own selling ability and the possibilities of his own corner of the field, and to make demands for a greater number of cars than he can profitably handle.

In any case, the maker about whom such reports are current, is placed on an insecure and treacherous footing thereby. Stories of voluminous output may lead to rumors of overproduction, on the one hand, or they may lead to over-confidence on the part of agents, to unwarranted volume of orders, and so to the glutting of the market. So long as the reports are exaggerated, there is danger of disaster from any and every quarter.

A point which is seldom considered in the retailing of such reports is that it takes a vast amount of time and money to prepare to manufacture on a really large scale. A big plant, expensive equipment, trained forces, unfettered capital, are some of the items which must be figured in forecasting an extraordinary output. Manifestly, in more than one case where such stories are applied, it is a physical impossibility for more than a moderate amount of material to be turned out in the course of a season. Consequently, unless a manufacturer is known to have more than ordinaily extensive facilities, reports of more than ordinary magnitude of production must be received with caution, and must be regarded in the

Digitized by Google

light of either an unfortunate circumstance or a mistaken policy. Always their effect is apt to be disastrous.

Psychological Aspect of Speed Problem.

To the student of psychology an interesting question is presented by the apparently honest declaration of motorists, who are arraigned in court charged with exceeding speed limits, that at the time of arrest, the vehicles which they were driving were not traveling at nearly so fast a speed as that specified in the complaint. Seldom indeed does the accused admit the rectitude of the assertion of the arresting officer, as to the time required to cover a measured distance. Invariably—one might almost say with truth, never—does the defendant in cases of this sort agree with the statement made by the policeman. The question therefore is, does the prisoner deliberately and intentionally lie, or is he making a plea to the court which he himself really believes to be honest?

To those who are familiar with the smoothness of the motion, with the lack of vibration and of noise which accompanies a well balanced, high powered car when traveling at a speed of 20 to 25 miles an hour, there is given an understanding of the reasons which may account for an honest difference of opinion between the officer and the motorist. The latter is influenced in his impressions by memories of many experiences in trolley cars and other vehicles, where, traveling at a much less speed than that with which he now is accused, his journeys were accompanied with noise, the rattle and bang of mechanism, loose bolts and other accompanying discordant sounds, which have become associated in his mind as almost synonomous with "speed." With these memories, which undoubtedly are not without their influence on his mentality, the motorist cannot believe that the easy riding, silent moving vehicle which he was driving could travel as fast, as is asserted by the officer, without at least a degree of discomfort to the occupants, which would compare in some measure with the recognized discomforts associated with rapidly moving vehicles of other sorts.

On the other hand, the statement of the officer contains assertions of the conditions under which the arrest was made, which, if true, prove conclusively that the arrest was justified. The policeman asserts that the car traversed a correctly measured distance within a certain number of seconds. He states that the time was noted on a watch especially designed for the purpose. If these statements are statements of fact there can be no question as to the guilt of the prisoner. True it is, that there are many known instances where the officer committed deliberate perjury. But it is equally true that the police seldom make unjustifiable arrests for exceeding the limit.

What, then, is the conclusion the layman is to form after reading the reports in the daily press of the number of motorists arrested for speeding, all, or nearly, of whom deny the accusation? Is he to conclude that all motorists are liars or that all policemen should be placed in that category? Or can he with justification, believe that each side of the controversy has stated an honest view of the matter? It is a curious condition of affairs and one which constantly is brought before the attention of the public. An explanation of the problem, based on the possible influence of "auto-suggestion," would be interesting, and the psychologist or metaphysician might discover in that way a solution which will be in refutation of the plaint of David, who said in his haste, "all men are liars."

Deodorization of the Exhaust.

Viewed in an unusual though none the less important light, the various improvements which are being wrought in the automobile tend above all to make it less offensive to the public from year to year. Improved carburation and better proportioning of the parts of the motor lead to a reduction in the noise of the machine; better gear construction has led to the elimination of the "songs" by which some of the better known makes of car used to be distinguishable even on a very dark night; improved muffler design and improved arrangements of the valve gears have served also to cut down the roar and clatter of the machines, while betterments in spring and body design have relieved the old offenses to the passengers, as well as to the man in the street. Even the nuisance of the odorous exhaust has been in part alleviated by the establishment of more perfect combustion in the motors, and the occasional elimination of over-lubrication. Actually, however, in the rationalization of the modern car, the sense of smell is about the only one of the human attributes which has been neglected.

It is very ridiculous at first thought, to consider at all seriously the possibility of removing the obnoxious qualities from the exhaust. When it is borne in mind, however, that abroad, laws are being enacted for this very purpose—since the visible fumes generally are the most disagreeable—that the smoke nuisance is one of the great est menaces to the health of great cities; and even more, that the popularity of the motor vehicle must increase in proportion to its inoffensiveness as well as its satisfactory performance, it must appear that even the purification of the exhaust, if it could be accomplished economically, would be of great value to the industry in the long run.

A method of accomplishing this by means of a simple and inexpensive scrubber has been invented in England, and is already on the market. Without opportunity to observe its working, it would appear that its use should be accompanied by no loss of power, and that the benefit derived from its use could not fail to be far and away beyond the cost of its installation. That some such arrangement, if not absolutely in that form, might be successfully devised, there is no question. As to the requirement for it, it is merely necessary to observe the improvement in silencing, and to note the high esteem in which silent running cars are held, to estimate the value to its user of such a device. In the last analysis, it is but extending the use and purpose of the muffler, which is no longer considered in the light of anything but an essential organ in the machine.

COMING EVENTS

July 3-4, Wildwood, N. J.—Motor Club of Wildwood's annual automobile carnival.

July 4, Douglas City, Ariz.—40 miles road race over city streets and country roads.

July 4, Pueblo, Col.—State Fair Association's meet at fair grounds track.

July 4, Glens Falls, N. Y.—25 miles stock car race at mile track.

July 4, Baltimore, Md.—Motor Car Racing Association's meet at Pimlico track.

July 4, Long Branch, N. J.—Elkwood Park Automobile Association's meet at Elkwood Park track.

July 4, Cape May, N. J.—Quaker City Motor Club's race meet and carnival.

July 9. Buffalo, N. Y.—Start of American Automobile Association's annual reliability touring contest for the Glidden and Hower trophies.

July 15, St. Paul. Minn.—Automobile Club of St. Paul's meet at Hamline track.

July 15, Huntington, N. Y.—Huntington Automobile Club's carnival and races.

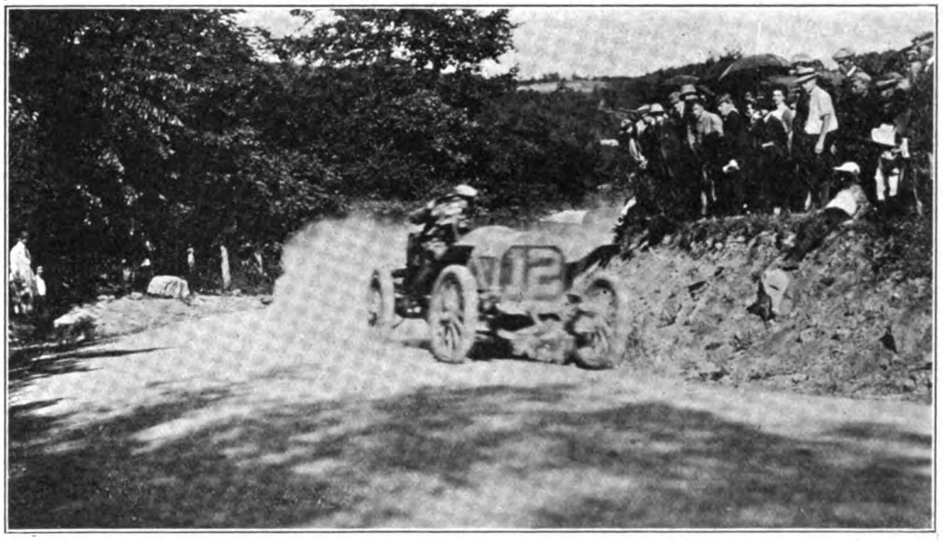
CARNIVAL SPORTS AT STROUDSBURG

Many Interesting Contests in Four Days' Meet—Fast Going in Hill Climbs—Gymkhana a Lively Final.



For the reason that the summer hotels are not yet even comfortably filled the four days' carnival promoted by the Monroe County Automobile Association last week in the vicinity of the Delaware Water Gap and Mount Pocono regions did not attract the big crowds that had been expected and therefore unusual enthusiasm did not develop. To be sure, fair sized crowds saw some of the events, but it was made up mostly of "natives" as the all year around residents are designated, reinforced by a sprinkling of summer boarders and waitresses.

FAR EXTENDING VIEW FROM CANANDENSIS HILL

The carnival began on Wednesday, 24th ult., with what was to have been a reliability endurance run starting simultaneously from New York City and Philadelphia, but only the latter part of the affair materialized. Quite a number of cars made the journey from Philadelphia to Stroudsburg, Pa. There were three classes to be decided from each city, these being distinguished between touring cars proper, roadsters and tourabouts and small runabouts. It was easy enough to find a winner in the latter class, inasmuch as H. McKay White, with a Ford runabout had the field all to himself. Class A, open to touring cars, presented an entirely different proposition. There were in competition Frank Yerger, Studebaker; W. F. MacGraw, Thomas; Walter M. Cram, Mitchell, Frank Hardhart, Jr., Elmore; and E. S. Shetzline, driving a car of his own design which he called the B. F. S. The 88 miles of give and take roads were covered by all except Yerger and MacGraw, with no penalties against them. The technical committee got to work to evolve a winner and the prize was awarded to the Elmore. Yerger lost his perfect score because he was held up by the police in Doylstown, and MacGraw was stopped by two fallen trees across the roadway. Class B was for roadsters and again the tied score predicament presented itself. George H. Stetson, Thomas-Detroit, and J. F. Brown, Autocar, finished with perfect scores, but the former's car survived the extra tests set by the technical committee and so was given the cup.

H. J. Kilpatrick came about as close to staring death in the face as he wants to in the hill climb up the Water Gap hill on Thursday, the 25th. Kilpatrick was the last to start in the free-for-all event and was going at the rate of a mile a minute when he struck a sharp curve half way up the steep hill. The big racing car skidded and banged into a telegraph pole, snapping it in twain. Kilpatrick was thrown out, but miraculously escaped injury, while the car was not damaged so badly but that it could be fixed up for the straightaway trials on the following day.

HARRY JONES (THOMAS) MAKING BEST TIME ON CANANDENSIS HILL

The Water Gap hill is 5,000 feet long and although there was a woeful lack of entries and spectators fast times were made by the cars that did run. There were two entries in the event for cars costing between $2,250 and $2,000, and a Rambler driven by W. F. Pierce beat J. A. Rutan's Jackson by nearly six seconds. The time of the former was 1:46⅗, and of the latter, 1:52.

H. D. Church, driving a Buick was the first car to make the ascent in the event for cars between $851 and $1,250, and he reached the summit in 2:22⅕. R. C. Rutan in a Jackson, came next and finished in 2:26⅕, but because a dog crossed his path he claimed another trial and lowered his time to 2:20. This resulted in another claim for a second trial by Church, and he made a spectacular run in 2:13⅗.

The Studebaker had practically no opposition in the class for cars selling between $2,000 and $3,000, covering the distance in 2:23⅗. The Thomas did not compete in the class for higher-priced cars and Jules Perigue, Zust, enjoyed a walkover in 2:04. In the free-for-all Perigue lowered his time to 1:57, which stood as a record for the course.

Friday, the third day of the carnival, was probably the most interesting day of all as there was a double bill—a series of mile time trials on the Pocono summit State road in the morning, and a hill climb on Canandensis hill in the afternoon for amateur drivers. There were no accidents during the time trials and only one mishap occurred while the hill climbing events were run, that being when Halstead Swan, of Brooklyn, was tumbled out of his car at a turn in the road. The course used for the hill climb is a twisting stretch of road about 1,500 feet in length, shaped something like a huge question mark standing on its head, the start being just below an S turn. The drivers had about 200 yards to get up speed before reaching the starting tape and Swan was traveling very fast as he began the

Digitized by Google

ascent of the extremely tortuous incline.

The road turns to the left about 50 yards from the start and Swan steered his car away to the right with the apparent intention of making a sweeping curve. He went too far over, however, and when he tried to turn to the left one of the wheels collapsed and the car turned over. Swan tumbled out of the seat as the machine went over and thus escaped injury.

The hill climbing events were held on a good stretch of State road, the grade being 10½ per cent., and fast times were recorded. Rutan, driving a Jackson, won the class for cars between $851 to $1,250, by reaching the tape in 42 seconds, but a big slice was made in this time in the following event, $1,251 to $2,000, when W. H. Pierce, Rambler, was clocked in 34⅘ seconds. J. E. Smith, Jackson, was second in 38⅘ seconds. Two Stevens-Duryea cars made the running in the class for cars selling between $3,001 and $4,000 that driven by T. J. Kitson winning in 34⅘ seconds, with Albert Scott only one-fifth of a second behind. This was the closest contest of the meet and both drivers were cheered when the times were announced.

Harry Jones, driving the Thomas Briarcliff car, made two trials in the free-for-all, scoring 30 and 32 seconds. The event for members of the Monroe County Automobile Association went to W. D. Church, Buick, in 43⅘ seconds, with A. C. Haney, Maxwell, second in 47⅘ seconds.

They were not eligible as regular contestants, but Kilpatrick, with his racing Hotchkiss, and Len Zengle, Pennsylvania, were allowed to make time trials. The former scored 24, 23⅕ and 23⅘ in his three trials, while Zengle made two fast runs in 28 and 27⅘ seconds.

Zengle and Kilpatrick starred in the mile time trials, in which the contestants had to cross a railroad track, Kilpatrick making the fastest time of the day in 48⅕ seconds. Zengle was second in 58⅘. The other drivers that competed in the free-for-all and their times were Harry Jones, Thomas, 1;07⅖; James Young, Zust, 1:13; and W. H. Pierce, Rambler, 1:25. Zengle won in the piston displacement class by covering the mile stretch in 58⅘ seconds. Swan was second in 1:02, and Jones third in 1:03⅗. Young was timed in 1:11, and Carton, Stevens-Duryea, in 1:09⅕.

W. H. Pierce in his Rambler, won the class for cars between 15 and 25 horsepower, his time being 1:16⅗. W. D. Church, Buick, was second in 1:23. The event for cars between 24 and 40 horsepower went to J. E. Smith, Jackson, in 1:16⅖, with W. B. Evans, Stevens-Duryea, second in 1:27⅖. Halstead Swan made the fastest time in the event for cars from 40 to 60 horsepower when he accomplished the mile in 1:00⅗. Young in the Zust was second in 1:16.

Several amusing gymkhana events held on a dusty half mile track was the program for the final day and had not the ticket takers become so interested in the events that they forgot their duty at the gate, the promoting organization would have sold more tickets. A large crowd of spectators was on hand, but most of them came through the unguarded gates while a hundred or more found the big holes in the fences convenient. The promoters could not understand this attitude either, as they had made the admission fee only 25 cents.

Eight interesting events kept the crowd in good humor. The first was a race to cover 880 feet in one minute, or at the rate of ten miles an hour. The slowness of a car traveling at ten miles an hour did not fail to make its impression, and two of the county supervisors took particularly good notice of the speed. This event was won by J. E. Smith's Jackson in 1 minute flat.

The next event was a potato race, where the driver had to dismount, find a potato in one of six tubs, transfer it to another tub, remount and proceed around the track. This was run in three heats on account of the number of entrants in one of the heats. Two Cadillacs gave a pretty contest, being neck and neck after the transference of the harmless but necessary potato. The winner in the final heat was the Buick, driven by H. S. Church.

The potato was again the butt in the third event. This time was was speared, and H. D. Gaines in the Zust speared best. Having done these stunts forward, reverses were given a chance. The Zust retired both speedily and gracefully, and its driver received the blue ribbon. An obstacle race furnished Church in the Buick an opportunity to show as pretty an ability to turn as had ever been witnessed. Snakelike movements between eight sets of barrels were made in the quick time of 45 seconds. An umbrella race, in which a passenger had to get out, grab a paper umbrella, get in and keep the umbrella open without tearing it or turning it inside out, resulted in another victory for the Zust's driver, who seemed unusually agile.

Kilpatrick made a remarkable exhibition when he covered the half mile track in 34⅕ seconds. Considering the dusty track the performance was phenomenal, but the driver declined to attempt to better this time, claiming that the track was too dusty to take any chances upon.

A polo game in automobiles wound up the meet, and it proved amusing. The cars carried two passengers, one of whom carried a polo stick. A rubber ball was kept in motion all the while and it was amusing to see the cars run around the field trying to locate the ball. T. E. Smith, in a Jackson, was the winner, but no time was obtainable as the timer had become frightened and headed for the hotel.

Move to Untangle the Foreign Situation.

For the purpose of unraveling the tangled foreign situation resulting from a misunderstanding of the relations existing between the American Automobile Association and the Automobile Club of America, president Hotchkiss, of the former organization, this week appointed a Committee on Foreign Affairs, to represent the governing body abroad. All of the five members named are either abroad at the present time, or will be in Europe at or about the time of the Grand Prix race at Dieppe, which occurs on the 7th inst. Those named for the mission are: W. K. Vanderbilt, Jr., Jefferson De Mont Thompson, A. G. Batchelder, S. A. Miles, and Robert Graves.

The present plan is to secure representation at the Ostend, which is to occur shortly when the entire situation will be brought officially to the attention of what is known as the International Association of Recognized Automobile Clubs. Such action has been deemed advisable, owing to recent reports which indicate that leading motorists on the other side are not familiar with the actual facts of the differences between the national body and the New York City local club with the national title.

"The committee has been given large powers," remarks Secretary Elliott, in regard to the situation," and it is believed will make it clear abroad that there is and can be but one national body in the United States; that no single club can be such national body; and that the national body is the American Automobile Association with its24 State associations, its 200 clubs and its registered membership of 20,000."

Dividing Traffic on a Paris Roadway.

One method of dealing with the problem of automobiles on the road was devised a little over a year ago by M. Lépine, Prefect of the Police in Paris, and while its success in the Champs-Elysees does not argue that it would be equally successful on narrower and busier thoroughfares, that success is interesting as an evidence of what some public functionaries can do to make conditions agreeable all around. The avenue is divided into three sections and the Prefect decreed that the center section should be used entirely for automobiles, and the two sides for horse-drawn vehicles. In addition to proving a success from the traffic point of view, it has also manifested the fact that motor cars cause less damage to the road than their equine rivals.

The Car that Excels the Camel.

When the Cole Brothers' circus arrived in Battle Creek, Mich., they found a progressive press agent who evidently enlisted their admiration for his ingenuity. The aforementioned P. A. was connected with the American Motor & Cycle Co. of Battle Creek—the Franklin agents in that city—and he induced the circus folks to permit him to decorate one of their camels with a banner on which was the legend that "while the camel can go without water for eight days, the Franklin motor car can go forever without water." All of which served to attract attention to air cooled cars in general and Franklins in particular.

FAST CLIMBING ON SKIPPACK HILL

Haupt Adds to His Laurels by Victories at Norristown Climbfest—Real Contests in all the Events.

By flying up the old historic Skippack pike, a slight incline with a rise of from 3 to 7 per cent., near Norristown, Pa., and covering 6,270 feet in 57⅗ seconds—a rate of 75 miles an hour—William Haupt of Philadelphia last Saturday, 27th ult., repeated his successes of Wilkes-Barre, Worcester and Cleveland and won the free-for-all event of the first annual hill climb of the Norristown Automobile Club, under a broiling sun and before a crowd of several thousand people.

THE STARTING POINT ON SKIPPACK HILL

Sixty-six cars entered for one of the greatest hill climbing contests ever held within a radius of 100 miles from Philadelphia, and there was a representative assortment of all kinds of cars and drivers to try for the diminutive cups that were offered in some of the events. The slight grade forming the road up the side of the hill of a valley renowned in history was in splendid condition for fast going, and with mountains in sight to the west, a peaceful pastoral scene below, with the usual property winding stream, the scene presented was very beautiful.

The arrangements were not as good as might be desired. After the officials had corralled all the competing cars into a paddock at the starting point it was discovered that the electrical timing apparatus stubbornly refused to do duty. They had to fall back on the telephone and split second watches. The crowd was too big for the State constabulary which policed the course and for a time a calling off of the events seemed inevitable. After the fourth event was run the officials waited until the guards could shoo the people into the paddock and stands before they went on with the next events.

Although Haupt's six cylinder hill climbing car made the fastest time of the day when he won the free-for-all in 57⅗ seconds there were other cars and drivers that earned laurels and whose performances commanded respect. One of these was the 48 horsepower Knox, driven by A. L. Dennison, to second place in 1:13⅗. Harry Goodin drove his Stearns in 1:16, and tied with J. W. Parkin in a car of his own construction. William Bourque in the little Knox was a close fourth in 1:16⅖.

There really were two free-for-all events. The one in which the fastest time of the day was made was for cars of any class or power and the other was for gasolene cars only, but as no steam cars appeared, both events amounted to practically the same thing. The one for gasolene cars only was also won by Haupt, but in slower time, 1:01, with William Bourque in the smaller Knox second in 1:15⅘. His team-mate, Dennison, was third, his time being 1:16.

The first machine to breast the upgrade was a Schact high-wheeled buggy driven by Applegate in the event for gasolene stock cars costing $850 and under, and naturally it attracted some attention. Applegate did not win the prize, although he reached the summit without faltering; the prize went to C. W. Mann, Buick, in 2:18. C. P. Brockway, driving an Overland won the event for cars between $850 and $1,250 by climbing the hill in 2:11. Mann was second and Stritzinger in a Mitchell third.

One of the most interesting events and one which brought out the high-powered and priced cars was that for gasolene stock cars over $4,000. William Borque, Knox, won out in 1:33, with W. J. Swain, Apperson, a close second in 1:37; George Davis in another Apperson, finished third in 1:38⅗.

Probably no driver at the meet felt more elated than Len Zengle when he won two brilliant firsts in the classes for cars from $2,001 to $3,000, and from $3,001 to $4,000. In the former event Zengle covered the distance in 1:36, and reduced this time by three seconds in the other event. Miller, in the Stoddard-Dayton, was the runnerup in both instances. The summaries:

Gasolene stock cars, $850 and under—Won by C. W. Mann, 18 Buick, time 2:18; second, J. F. Graham, 15 Ford, 2:24; third, R. S. Heebner, 15 Ford, 2:37; J. W. Lewis, 18 Buick, 2:59¼; B. Applegate, 14 Schacht, 3:41⅕.

Gasolene stock cars, $851 to $1,250—Won by Brockway, 24 Overland, 2:11; second C. W. Mann, 18 Buick, 2:16⅗; third, B. F. Stritzinger, 24 Mitchell, 2:31; Harry Greenwood, 20 Reo, 2:38⅕; H. W. Trump 22 Auburn, 2:44.

Gasolene stock cars, $1,251 to $2,000—Won by W. J. Hays, Jr., 35 Jackson, 1:53; second, Brockway, 24 Overland, 2:05⅗; third, T. W. Berger, 35 Oldsmobile, 2:15; B. F. Stritzinger, 35 Mitchell, 2:26.

Gasolene stock cars, $2,001 to $3,000—Won by Len Zengle, 50 Pennsylvania, 1:36; second, A. C. Miller, 45 Stoddard-Dayton, 1:38⅖; third, W. J. Hays, Jr., 35 Jackson, 1:41⅖; J. J. Coffey, 29 Columbia, 1:46; L. J. Block, 40 Ford, 1:54; T. M. Twining, 50 Crawford, 2:05; R. H. Morris, 30 Acme, 2:07⅕.

Gasolene stock cars, $4,001 and over—Won by William Bourque, 30 Knox, 1:33; second, C. J. Swain, 55 Apperson, 1:37; third, George Davis, 55 Apperson, 1:38⅗; J. W. Parkin, Jr., 30 Packard, 1:48.

Gasolene stock cars, $3,001 to $4,000—Won by Len Zengle, 50 Pennsylvania, 1:36; second, A. C. Miller, 45 Stoddard-Dayton, 1:38⅗; third, Alan Wood, Jr., 40 Pope-Toledo, 2:10.

Free-for-all, gasolene cars of any price, flying start—Won by William Haupt, 50 Great Chadwick Six, 1:01; second, Bourque, 30 Knox, 1:15⅘; third, Albert Dennison, 48 Knox, 1:16; A. C. Miller, 45 Stoddard-Dayton, 1:18; J. W. Parkin, Jr., 60 Parkin, 1:18⅗; H. W. Harding, 60 Matheson, 1:19⅗; Len Zengle, 50 Pennsylvania, 1:20; Harry Gooden, 60 Stearns, 1:21; T. W. Berger, 40 Oldsmobile, 1:21⅗; J. J. Coffey, 29 Columbia, 1:23; C. J. Swain, 55 Apperson; 1:25; George Davis, 55 Apperson, 1:27; A. A. Jones, 15 Ford, 1:50.

Free-for-all, cars of all prices, flying start—Won by Willie Haupt, 50 Great Chadwick Six, 0:57⅖; second, A. L. Dennison, 48 Knox, 1:13⅖; third, tied, Harry Gooden, 60 Stearns, 1:16, and J. W. Parkin, Jr., 60 Parkin, 1:16; William Bourque, 30 Knox, 1:16⅖; A. C. Miller, 45 Stoddard-Dayton, 1:17; Len Zengle, 50 Pennsylvania, 1:18⅖; H. N. Harding, 60 Matheson, 1:20; T. W. Berger, 40 Oldsmobile, 1:22⅕; George Davis, 55 Apperson, 1:23⅘; C. J. Swain, 55 Apperson, 1:24; Jones, 50 Jones Corbin, 1:52.

ROBINSON MAKES FASTEST TIME

Driver of Stevens-Duryea Car Hero of Rockville Hill Climb—Exciting Events Thrill Enthusiastic Crowds.

P. J. Robinson, driving a Stevens-Duryea "bix six" made the fastest time at the hill climb promoted by the Automobile Club of Rockville, Conn., on Tuesday afternoon, 30th ult., which meet was the feature of the Old Home Week celebration at Vernon. Robinson's time in the open for gasolene cars was 41 seconds, at the rate of more than a mile a minute for the distance of seven-tenths of a mile, and he won the free-for-all in 43⅘. The light six car of the same make finished second in the free-for-all in 49⅕, and ran third in the open for gasolene cars in 48⅖ seconds.

The meet was well conducted and the application of a special treatment for allaying the dust worked perfectly. The militia guarded the course and did their work well, as did the police with whom they worked, and the crowd though numbering several thousands, was easily manged. Not an accident occurred to mar the meet, as there were no bad curves on the course.

MacDonald started the ball rolling when he drove his little Maxwell up the incline in 1:21. Then came the Cameron car in 1:18⅘, but the crowd got its first thrill when a little Ford runabout went up in the remarkably fast time of 1:05⅗, figures that were not touched for three classes. Louis Elmer piloted the last named.

"Barney Oldfield" Peard, so-called because he always drives with the butt of a cigar in his mouth, started the event for cars between $851 and $1,250 by running his Overland to the finish in 1.20¾. Robert Miner, Buick, followed in 1:07, which won the event. The Cameron was timed in 1:10, and the Maxwell in 1:17. The next event was also for small cars and Elmer and his Ford carried off the honors, but his time was slower than in the first event, being made in 1:08⅗. The Maxwell did it in 1:13½, and the Cameron was timed in 1:14⅗. Claude Pinney in another Maxwell finished in 1:20.

The real excitement began in the event for cars between $2,001 and $3,000, when C. D. Alton, Jr., started things by driving his Columbia in 1:04⅘. Then came W. A. Bourque in a Knox, and when he whizzed up in 50¾, the crowd "Oh'd." Harry Tuttle followed in 54⅗, and a Buick in 1:07⅖, when S. A. Miner's Knox dodged below the minute again with 57⅘. Lorimer, in the Thomas-Detroit "Bluebird" got a noisy hand when he appeared to knock Bourque's time to smithereens, but he missed the mark by one-fifth of a second. Robert Ashwell took a pleasure trip up the hill in 1:15⅕, and Charles B. Tiley, in a car of his own make, was timed in 1:06⅖. Swan's Corbin made a fast run in 53 seconds, and W. T. Plimpton covered the distance between the tapes in 58⅖; he drove a Pope-Hartford car.

From point of rivalry the most exciting event of the day was that for cars from $3,001 to $4,000, as four cars—the Knox, Thomas-Detroit, Corbin and Stevens-Duryea little six—ran neck and neck and made, respectively, the times of 50, 50⅕, 50⅖ and 50⅗. Tuttle in the Stoddard-Dayton, was timed in 54⅕, and E. J. Blake's Pope-Hartford was caught by the timers in 59 seconds.

The free-for-all opened slowly with Seymour's Thomas in 1:01⅕, and Merten's Columbia in 1:03⅖, and Bourque caused a thrill when he finished in 50 seconds. Tuttle made the run in 53⅕, and Blake's time was 59⅗. All bets were off when the Stevens-Duryea "little six" then went the distance in 49⅕, and when Robinson followed in the "big six" of the same make, the country folk went crazy with the excitement. The time was 43⅘. The Corbin closed the event in 50⅖ seconds.

It was the last event of the day—the open for gasolene cars—in which Robinson made his phenomenal run and shattered all the previous times made for the climb. Robinson went so fast that he nearly slewed off the road at one place and he slowed for a fraction of a second, but his time—41 seconds—was the best piece of work at the meet. Bourque made a desperate effort but could do no better than 44⅕, while the other Stevens-Duryea got third prize in 48⅖ seconds. Two Corbins went up in 49⅘ and 50⅕, respectively, while O'Laughlin's Pope-Hartford and another Knox did 49⅕. The two Columbias did 51⅗ and 50⅕.

Chicago Club Declines to Secede.

Another demonstration of the sincerity of the "best wishes" which the Automobile Club of America tendered the American Automobile Association on its withdrawal from the latter organization, is supplied by the intelligence of its recent attempt to induce the Chicago Automobile Club to sever its connection with the governing body and join the outlaw movement. In response to the invitation, the Chicago club passed a resolution of non-acceptance, which was published this week in the following unmistakable terms:

Resolved, That the Chicago Automobile Club respectfully declines the invitation of the Automobile Club of America to withdraw from the Illinois State Automobile Association, and thereby from the American Automobile Association and to join with the Automobile Club of America in an effort to control American motor racing.

This is a second number in the program which was opened last week by the statement published in local papers to the effect that emmissaries of the A. C. A. (of New York City) were at that time in Louisville, Ky., endeavoring to procure the secession of the automobile club of that city from A. A. A. control.

SEALED BONNET CONTEST EASY

Sixteen Perfect Scores in Delaware Association Run—Minor Mishaps Eliminate Five Contestants.

Sixteen perfect scores by the 21 contestants entered was the record made by members of the Delaware Automobile Association in their first sealed bonnet run held last Saturday, 27th inst. The run was from Wilmington to Valley Forge, Pa., and return, a distance of 79 miles on a time schedule of 5 hours 42 minutes. The five cars that failed to finish were put out of the running only through minor mishaps.

The perfect scorers in order of finish were: Albert Rothschild, Ranier; James F. Hoey, Buick; Joseph H. Shaw, Franklin; Studebaker company, Studebaker; J. R. Richardson, Mitchell; James T. Chanler, Mitchell; J. R. Richardson, Mitchell; Eugene E. DuPont, Thomas; William H. Jones, Rambler; William E. Hilland, Ford; Robert R. Glover, Maxwell; Henry McComb Banks, Stoddard-Dayton; Dr. John C. Fahey, Maxwell; William C. Corey, Mitchell; Eugene DuPont, Peerless, and Eugene Du Pont, Pierce Arrow. Dr. Howell, Mitchell, and J. W. Matthews, Garford, were disqualified for breaking the seals. The points assessed against the unsuccessful contestants were as follows:

George A. Elliott, Pierce Arrow, 2 points; Dr. H. W. Howell, Mitchell, 86; John T. Thompson, Buick, 58; J. W. Matthews, Garford, 90, and LaMont DuPont, Packard, 17.

The weather was perfect and the conditions so easy that all but three of the cars arrived at Upland on schedule time of 50 minutes. The late arrivals were Elliott, Dr. Howells and La Mont Du Pont. At the second checking station at Valley Forge, the turning point, Dr. Howells was 27 minutes late, Thompson one minute, and Matthews 30 minutes late.

The tourists carried their luncheon boxes with them and lunched at Washington's headquarters at the old camping ground.

The return to Wilmington was accomplished without incident, the last car arriving before 4 o'clock. The Wilmington club, whose chief object in promoting competitive contests of the sort is for the pleasure to be derived from them by members, intends to hold another contest at a longer distance in August.

New Jersey Club Moves to New Home.

The New Jersey Automobile and Motor Club of Newark moved from their old quarters at Broad and Chestnut streets on Tuesday, 30th ult., into a spacious new club house on the corner of Park Place and East Park street. The new quarters contain the usual fittings and arrangements necessary to the comfort and convenience of automobilists when off the road.

SHAPING UP FOR GLIDDEN TOUR

Chairman Hower Appoints His Officials—Entrants Anticipate More of a Contest Than in Previous Years.

With the approach of the date for closing the entries for the Glidden Touring Contest, which starts from Buffalo, N. Y., on the 9th inst., the organization of that event is fast assuming tangible proportions. Although the lists will close to-morrow (Friday), the number of entries received up to Wednesday night for the tour proper, totalled only 20, while 7 runabouts had been enrolled as contestants for the Hower Trophy. The usual "eleventh hour" rush of late entries, however, is expected to swell the list to more imposing proportions.

Chairman Hower of the touring board of the American Automobile Association, this week announced the names of the following officials who are to administer the contest under the superlative rule:

Dai H. Lewis, secretary of the A. A. A. Touring Board, in charge of the confetti and pilot car; E. L. Ferguson, starter; Mortimer Reeves, checker at the finish and in charge of night controls; F. D. Stidham, chief of observers; H. D. Herr, hotel arrangements; Devid E. Hoag, M. D., official surgeon; Arthur Jervis, press representative; W. L. Conklin and W. A. Carroll, watchers.

Observers will be carried this year, and this fact, coupled with one or two features injected with the revision of the rules and the nature of the course chosen, have led to the general conviction that the forthcoming contest will be far more rigorous than those which have preceded it. This sentiment is voiced by J. E. Walker, of the H. H. Franklin Mfg. Co., in explanation of the appearance of Franklin cars in the tour this year for the first time. "The reason we never made entries in these events before," he said, "was because we felt that generally it was more of a tour than it was a contest. We believe, however, that the machine that covers the course this year with a perfect score will be put to a severe test."

Despite the recent ruling of the A. A. A. barring women from competition in its racing events, the name of Mrs. Joan Newton Cuneo is likely to figure as conspicuously as heretofore in the reports of the contest, and her name already is enrolled. The Glidden contest not being regarded in the light of a race, the sex discrimination does not apply. That it will be entirely free from the racing element which has characterized former events which have borne the same designation, however, is not assured.

The final arrangement of the course leaves a total distance of approximately 1,700 miles to be traversed during the 15 days of the contest. In tortuousness, picturesqueness and difficulty of achievement, the route, which traverses seven different States, seems likely to prove at once the most difficult from the driver's standpoint, and the most enjoyable from that of the passengers, yet proposed for an event of this nature.

Many to Attend Good Roads Convention.

With 79 miles of modern highway in actual course of construction near the city, the delegates to the National Good Roads and Legislative convention to be held under the auspices of the American Automobile Association, in Buffalo, N. Y., on the 6th, 7th and 8th, insts., will be afforded an invaluable opportunity of learning the practical side of road making, which will be of immense importance to the users of the highways throughout the entire country. This demonstration will afford highway officers, contractors and others present an unusual object lesson for the work comprises the construction of highways of brick, macadam and gravel so that a fund of information covering the entire breadth of the subject of road building will be placed at the disposal of the 2,000 delegates and visitors for whom the reception committee have made preparations.

The convention has grown to proportions hardly expected by its promoters. Indeed, it promises to be an event of unusual importance to the community at large.

Delegates have been appointed by the automobile clubs affiliated with the American Automobile Association in a chain of organizations reaching from coast to coast,and representing the following cities: Los Angeles, Cal.; Newark, N. J.; Springfield, Mass.; Elyria, Ohio; St. Louis, Mo.; Wilkinsburg, Pa.; Philadelphia, Pa.; Chicago, Ill.; Bridgeport, Conn.; Wilkes-Barre, Pa.; Malden, Mass.; Washington, D. C.

The National Committee in charge of the convention consists of Robert F. Hooper, Philadelphia, chairman; ex-Governor N. J. Batchelder, of New Hampshire; Alfred Reeves, of the A. M. C. M. A.; William R. Hotchkiss, president of the A. A. A.; Charles Thaddeus Terry; James H. MacDonald, president of the American Road Makers Association, and Frank B. Hower. Co-operating with these committees will be the national officers of the three A's.

Rheineck to Pilot the Racing White.

Announcement of the retirement of Walter C. White from the list of racing drivers is followed by the naming of Walter Rheineck as his successor in the piloting of White steam cars in all contests of speed and endurance in which hereafter they may be entered. Rheineck for some time has accompanied White in his racing contests, serving as a mechanicien, but is said to have thoroughly mastered the problems connected with driving the White in competition contests, and, in addition, he is credited with the possession of the right quality of nerve.

ONLY FIVE ESCAPE PENALIZATION

St. Louis Reliability Run a Strenuous Contest Over Rugged Roads—It Develops a Hero and "Heroette."

Two candidates for Carnegie medals or some other kind of honors evolved from the second annual owners' reliability run for the Hagerman trophy, promoted by the Automobile Club of St. Louis last Saturday, 27th ult. One was a hero and the other was a "heroette." Oddly enough the "hero" was Chief of Police E. P. Creecy, the oldest entrant in the contest, who despite all kinds of trouble, finished the run That is why they speak of the Chief as a hero in St. Louis this week. The "heroette" was Miss Ida Britton, who drove a 50 horsepower Pope-Toledo over the tortuous course of 110 miles to De Soto and back, carrying seven persons, with a loss of only two points, inflicted for premature arrival at the first control.

Twenty cars started from the headquarters of the club between 8 and 9 o'clock in the morning, and of this number all but three finished the run, but three of the finishers were later disqualified. The run was not a parlor car ride by any means. At their best the famed De Soto roads are noted for their hilliness and are not easy to negotiate even when they are in prime condition, which certainly was not the case on Saturday. The rains had washed the notorious hills out until many of them were more like rocky gullies placed laterally than parts of the highway. The drivers were all amateur owners, men who do not sell, make or drive cars for money.

The reception given by the country people and citizens of the towns along the course was most enthusiastic. The farther south the tourists went the more enthusiastic was the reception accorded them. There were large crowds waiting at Hillsboro and when De Soto was reached a crowd of about 2,000 lined the streets.

After the cars had finished they were put under a thorough test and examination by the technical committee and it was found that Walter McKittrick, Locomobile; Samuel Plant, Packard; Charles E. Bascom, White; C. M. Barnard, White, and Ralph Smith, Matheson, had received no penalties. With the exception of this quintet the nearest to a perfect score was Miss Britten, who was penalized two points for premature arrival at the first control. P. E. C. Ball was penalized for arriving late at the first control, but he has protested the decision, claiming that the distance was improperly measured. He drove a White.

T. G. Sommermeier, Kisselkar, was penalized for stopping his engine and for inspections of this car and the committee found his brake test not as good as they thought it should be. J. E. Huiscamp,

Digitized by Google

Ford, after making a satisfactory run until within a few miles of the finish, ran out of water and "froze" his motor. George Steffens stopped a few minutes to put a fan belt on his Cadillac and that knocked him from the perfect score division. Chief Creecy, Stanley, lost his way several times and a leaky engine packing caused him to lose many points. J. C. Graham, White, withdrew after finishing and did not go through the outside tests and examination.

If Dr. W. W. Graves had not been delayed 19 minutes with an overheated engine, he and his Ford would have gotten into the honor class, as otherwise he had a perfect score and the car survived the tests of the committee. M. F. Bingham, White, was dropped from the honor brigade just because he had assistance in getting water for his car, otherwise he would have had a perfect score. W. J. Kinsella put in a claim for the leather medal for the greatest number of punctures. Kinsella patched up eighteen of them before he decided to withdraw.

W. M. Grayson, Stoddard-Dayton, did not appear for the outside tests and for this he was disqualified, while Robert Walsh , Thomas, withdrew during the final tests. Previous to this he had been penalized 25 points. Edward Walsh, Packard, was penalized for an involuntary stop. These were all the finishers.

American Entry Regains the Lead.

America once more is in the lead in the "race" from New York to Paris. The Thomas car, as announced by cable from the Times correspondent, caught the German Protos on Monday, 29th ult., just before noon and passed the Teutons before reaching Kainsk. Shuster got the American car away from Tomsk at 4 o'clock Sunday morning, being then just fifteen hours behind the Protos car. The pursuit was over roads that at first were little better than a plowed mud field, but better roads were reached by afternoon, and Shuster determined to run all night if necessary to regain the actual lead, Miller relieving him at the wheel at intervals.

The German car was sighted ahead at 10 o'clock Monday morning, with a lead of only two miles. Then ensued an exciting race, Lieutenant Koeppen crowding his car to keep ahead, while Shuster was just as determined to pass his rival. When the American machine finally was right upon the German machine, Koeppen turned aside to allow it to pass, and the lusty shouts of the triumphant Americans elicited hearty responses from their rivals. The Thomas car arrived at Omsk on Tuesday making the run from Irkutsk to that point in four days less time that was required by Prince Borghese with the Itala car in the Peking-Paris race of last year.

By a special dispatch to a London paper on the 1st inst., the Italian Zust car was reported at Chita. It still is more than 2,000 miles behind the Thomas.

ZIG-ZAG CLIMB UP DODSON HILL

Kansas City Gets Satisfying Glimpses of Exciting Contests—Brooks the Only One Winning Two Events.

If the thousand and more spectators who stood around the Dodson hill near Kansas City on Saturday, 27th inst., had been in enough balloons to hold them and anchored about a half mile above the aforementioned hill they would have seen an interesting contest—the annual hill climb of the Kansas City Automobile Club. As it was, those who attended the contest had to content themselves with as much of a view of the event as they could get either from the start or finish because the road is so crooked that at no place is more than 100 yards of the route visible from the road. However, those who saw only the starts came away satisfied, and those who saw only the finishes equally were well pleased.

There was only one hitch in the program, While the contests were going on a man with a long beard and a determined manner insisted on driving up the road in a buggy. The guards intercepted him, but he was not to be detained.

"I'm a rural mail carrier and you can't stop me," he said. "If you don't let me pass I'll have the law on the whole lot of you."

The contest was delayed several minutes while he and his decrepit nag ambled slowly up the hill.

Honors were well distributed between all the cars except the Stoddard-Dayton driven by A. O. Brooks. He won two class events and in the free-for-all made the fastest time, covering the sinuous half mile in 59⅗ seconds. Fletcher Cowherd and his Corbin cars had hard luck from early morning. While practising on the hill his car bumped into another and the former was completely disabled. Cowherd borrowed another car and went into the free-for-all. He made a fast start, but suddenly stopped—he had forgotten to turn on the gasolene. In the second attempt something got into the carburetter and Cowherd gave it up in disgust. The summaries:

Runabouts costing up to $850—Won by S. H. Easterday, Ford, 1:36; second, J. A. Hilsman, Maxwell, 1:54; third, Harry Hathaway, Maxwell, 2:19.

Runabouts costing $851 to $1,250—Won by George Gibson, Reo, 1:35⅕; second, E. L. Weiant, Buick, 1:51⅕; third, William Davis, Buick, 1:52⅕; fourth, G. M. Breed, Buick, 2:46.

Runabouts costing $1,251 to $2,000—Won by E. Nason, Stoddard-Dayton, 1;31⅕; second, W. S. Hathaway, Maxwell, 1;32⅕; third, Charles Levendoski, Maxwell, 1:39⅖.

Runabouts costing $2,001 to $3,000—Won by A. O. Brooks, Stoddard-Dayton, 1:06⅕; second, Gordon T. Gealam, Pennsylvania, 1:34⅘.

Touring cars costing up to $2,000—Won by J. C. Powellesson, Jackson, 1:29⅖; second, C. J. Corkhill, Oldsmobile, 1:34; third, Charles Levendoski, Maxwell, 1:41; fourth, J. P. Ledwidge, Great Western, 1:43⅗; fifth, Harry Hathaway, Maxwell, 2:16⅕.

Touring cars costing $2,001 to $3,000—Won by E. L. Weiant, Buick, 1:13⅕; second, Don Cole, Oldsmobile, 1:15; third, H. Holxhauer, Pope-Hartford, 1:17; fourth, Joseph Matson, Corbin, 1:17⅘; fifth, Gordon T. Beaham, Pennsylvania, 1:47.

Free-for-all—Won by A. O. Brooks, Stoddard-Dayton; second, tie between Don Cole, Aldsmobile, and R. C. Greenlease, Thomas Flyer, 1:07; fourth, L. Scott, Stanley, 1:09⅕; fifth, E. L. Weiant, Buick, 1:13⅖; sixth, O. W. Hiatt, Buick, 1:18⅕; seventh, Charles Levondoski, Maxwell, 1:30⅕; eighth, G. M. Beed, Buick, 1:30⅖; ninth, W. S. Hathaway, Maxwell, 1:33⅕; tenth, Joseph Maston, Corbin, 2:54. In the runoff for second place the Thomas won in 1:08 as against 1:11 for the Oldsmobile.

Electrics—Won by Detroit, 2:35.

Scorcher's Confession Amazes the Bench.

Herman Kilpatrick, who can drive an automobile fast enough to take one's breath away, can tell the truth about it with a readiness that rendered Judge Fleming almost breathless in the Court of Special Sessions at Jamaica, L. I., on Tuesday, 30th ult. Justices O'Keefe and Ryan shared in his astonishment.

"This man, your honors," said Motorcycle Policeman Ennis, as he presented his prisoner, "was riding sixty miles an hour in an automobile on Hillside avenue on June 3, in the afternoon about 6 o'clock."

The Justices looked over their glasses at Kilpatrick, whose home is in Manhattan. Judge Fleming lives in Jamaica and does not like swift moving motor cars.

"Do you mean actually that he drove a car sixty miles an hour through a Jamaica thoroughfare?" he gasped.

"Oh, yes, your Honor," admitted Kilpatrick, "and then some. I was going a great deal nearer ninety miles than sixty miles."

Judge Fleming sat back in his chair and fanned himself. When he had convinced himself that it was not a sunstroke, but that a driver was really admitting running at a mile and a half a minute, he inquired into the circumstances.

Kilpatrick was the driver who broke all the world's records for road racing at Jamaica June 5 and 6. It was while trying out his car two days before the races that he was arrested. He explained to the court that in all other events the course had been open for trying out between the hours of 5 and 7, morning and evening, a few days before the races, and that he has supposed the same rules applied in the Jamaica races. Judge Fleming has a strong regard for a man who dares tell the truth, and he joined in voting to impose upon Kilpatrick a fine of only $25.

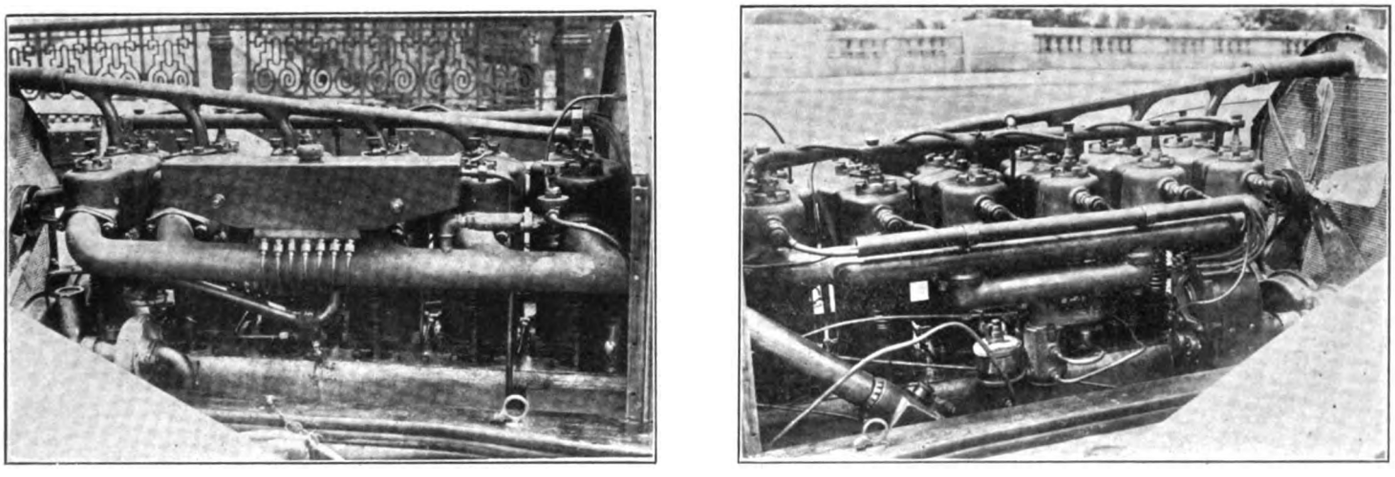
THE PALMER-SINGER "SIX-SIXTY"

New Model of Close-to-the-Ground Type Makes Its Appearance—Its Compact and Sturdy Power Plant.

If there is any truth in the notion that the speed of a car is indicated to a great extent by its appearance, then owners of the new Palmer-Singer "Six-Sixty" car never should have occasion to miss important engagements through lack of ability on the part of the car to cover ground at any speed which may be required of it in reason. The fact that its maximum speed is modestly alleged to be no less than 90 miles an hour, lends point to the conclusion.

Although announced prospectively some time since, the first of the new six-sixties has been on the road but a few days. As the accompanying picture indicates, it is of the close-to-the-ground type of fast cars, a goodly number of which are making their appearance this year. This means, that without sacrificing road clearance, the center of gravity has been brought low enough to make high rates of speed much safer than with the ordinary touring car. The sweeping fenders and low body construction, cut down wind resistance as well, while adding to the racy appearance of the machine, which is a substantial addition to the line of the Palmer & Singer Mfg. Co., New York City.

from the tank to the bearings, with pumped return from the crank case. The low lying manifold, leading from the carburetter without any appreciable length of uptake, is noteworthy, as is the arrangement of the Bosch Magneto and the wiring for the dual ignition system. As is implied by the designation of the car, the motor is rated at 60 horsepower. Its cylinder dimensions



PALMER-SINGER "SIX-SIXTY"

are 4¼ inches bore and 5 inches stroke.

Transmission of the power is secured through the medium of a multiple disc clutch, four-speed, selective type, change gear, fully enclosed cardan shaft, and full floating axle. The transmission parts are

2⅛-inch spokes of specially selected stock, and shod with 4-inch tires, front and rear. The suspension is by semi-elliptical springs, the front members being 34 inches in length, and the rear ones, 52 inches. The control mechanism includes the conventional steering wheel mounted, motor regulating levers, clutch and brake pedals, and an accelerator pedal, for convenience in handling under close traffic conditions. As shown in the illustration, the steering wheel is mounted on a column, well inclined, and is elevated sufficiently to give the operator ample mastery of the car, and a low racing position.

The chassis may be obtained with some

SIX-SIXTY MOTOR, SHOWING EXHAUST AND INLET SIDES

The compact and sturdy nature of the power plant is well illustrated in the views showing it from either side. Among the points which are at once observed are the compact arrangement of the oil tank on the exhaust side of the motor, which by the way, reveals in addition only the water circulating pump and the check valve for the pressure fuel feed, which is mounted on the exhaust manifold. The lubrication system, it should be observed, is by direct feed universally mounted on ball bearings of the "F. & S." type. The brakes are all enclosed, and mounted in dust-proof cases on the rear wheels. Contrary to a custom which is pretty general, however, they are not of the expanding and contracting order, but are both expanding. Both sets are balanced by compensating levers, and they are applied by pedal and lever

The wheel base is 118 inches, and the wheels are 34 inches in diameter, built with little variety of body mounting, all in line with its purpose as a road flier. With the plain runabout body, with single rumble seat in the rear, it lists at the $2,850 mark, which, considering the amount of high-grade material involved in its manufacture, is a figure worth noting. A double rumble for the rear, may be had at an advanced price, while $3,200 is asked for the light touring equipment with "baby" tonneau, shown in the picture.

UNIT SYSTEM OF TRANSMISSION

Beemer Explains Its Saving of Power—Results of Test Experiments and His Deduction from Them.

Whatever may be said of the success of the motor car in a general way, the fact remains that a number of problems incidental to its design remain to be solved in a manner which is wholly satisfactory to the engineer. One of these is the transmission problem. Numerous attempts have been made to produce results which combine the desired flexibility and controlability with the reliability and simplicity which are absolutely essential in a motor car. Among these the so-called unit type of transmission is being accorded a growing amount of favor.

This system, in a word, involves the combination of the change speed mechanism with the live or floating type of axle, all enclosed in a single housing, which also forms the bridge or supporting member carrying the load of vehicle weight. With this arrangement power is carried to the group through a single cardan shaft, and but two essential organs are thus required for the power plant, namely the motor and axle unit, where three or more may be required with other systems. Speaking of its advantages, in a paper read before the Society of Automobile Engineers last week, Frank Beemer remarked that there are a number of reasons why this system should and does save considerable power. The first is, as he explains:

"That it requires but one universal joint, either single or double. This is one of the points which, most engineers agree, consumes considerable power, while the driving at various angles of the propeller or cardan shaft, through two or three universal joints, is also very undesirable. The transmission applied on the rear axle allows the universal joint to be placed immediately back of the clutch and a considerable distance forward of the point where it would be placed in a car, with the transmission carried on the sub-frame, thus reducing the angularity of the propeller shaft to a minimum, and in most cases bringing it practically on a straight line with the crank shaft.

"The transmission and differential mechanism being placed in a single housing makes it very easy to have it in perfect alignment; this is one of the features that has proven from all experiments to be the principal factor in the saving of power. It is quite necessary, and has been recommended by all ball and roller-bearing authorities, that to obtain the best results from the use of any type of anti-friction bearing it is absolutely necessary, that the bearings be in perfect alignment. This question has been taken up in a very practical way, and it has been found that the unit system of power transmission permits freer action to the bearings, thus reducing the effect of abnormal shocks and vibration to the bearings.

"The tests that have been made of this system of transmitting power show a saving of from 16 to 20 per cent. of the power applied, or, in other words, it utilizes this much more power at the driving wheels, in the ordinary designs, this amount being consumed by universal joints, angularity of cardan shaft, disalignment of bearings, and many other sources of imperfection which are more easily taken care of in the transmission type of axle than in the various types of plain axles commonly used.

"The automobile buyer of to-day in most cases considers very carefully the simplicity of the car, more than its style or appearance. He is not repeating the troubles which were experienced in the early days of automobiling, when many purchasers endeavored to secure a car which, in plain language, consisted of the greatest number of pieces for the money. It is a well known fact that where the acme of simplicity lies is the maximum of durability.

"The automobile equipped with the unit system of power transmission has been taken by many reliable engineers as a parallel to the direct connected power set or unit found in the latest power plants, having the engine, which corresponds to the automobile motor, and the generator, which is the equivalent of the transmission devices. This has been found to be the most practical and economical method of producing electricity, and it is this idea, carried out, as herein described, that forms one of the most economical ways of transmitting the power of an automobile motor to the road wheels through a system based on mechanical principles. It should appeal to most engineers as being one of the best and most practical methods of obtaining the result desired.

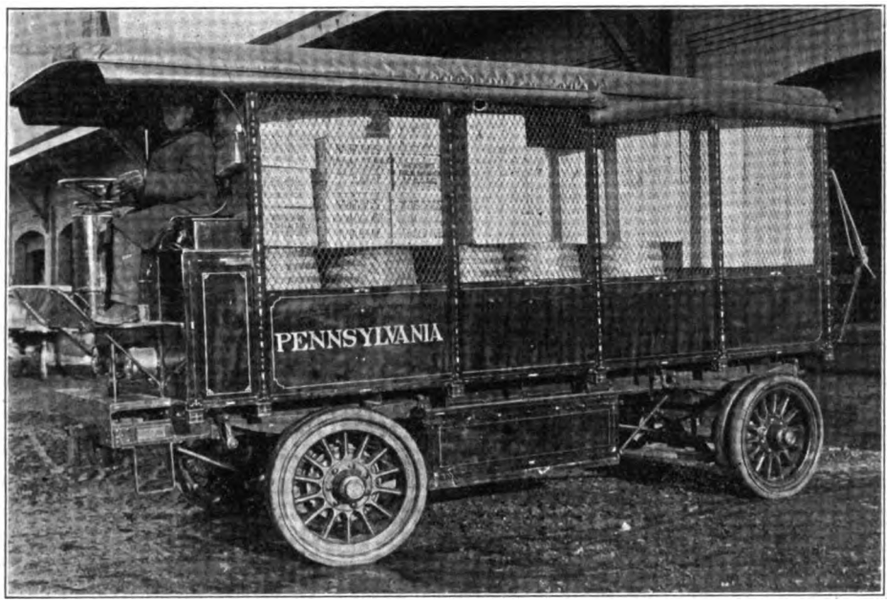
"The saving of power, as above stated, is based principally upon hill-climbing tests which were made with several cars equipped with the unit transmission system. I have been present at a number of these tests, and have driven some of these cars, which were equipped with the transmission on the sub-frame, and have noted carefully the working of all parts of the car. I have also taken the same cars equipped with the transmission axle and in repeating the same tests have found that there is a very considerable increase in both speed and ease with which the motor will handle the car on the same hills.

"I have also made certain speed tests with a car, with all parts in good condition. The motor at its very best was unable to secure on good roads more than 40 to 45 miles per hour, while the same car equipped with the transmission axle and with all conditions as nearly alike as possible would develop, with ease, 55 miles and even as much as 60 miles per hour. These and other efficiency tests tend to prove that the unit system of power transmission is without question one of the long-looked-for improvements in automobile design.

"There are a number of arguments advanced in favor of the side chain drive for heavy cars. A car equipped with this drive, all adjustments being as correct as they were intended to be by the designing engineer, will prove efficient to a certain degree. There are, however, a number of annoyances connected with this system of propelling a vehicle that are very unpleasant; the principal one being the noise caused by the chains. It is essential, in this design, to have what is commonly called a radius rod to insure the proper distance between the centers of the sprockets. These are frequently adjusted to different distances between the centers of the sprockets. These are frequently adjusted to different distances, causing the chain to ride on the side of the sprocket, adding undue wear.

"There are a large number of cars equipped with this system that are not provided with cases to protect them from dust and dirt, which quickly cause an extreme amount of wear, as the accumulation of dirt upon these parts absorbs the oil or grease used for lubrication, and it is only a matter of a short time until the correct pitch of the sprocket and chains are destroyed, and it is at this time that the greatest inefficiency must arise. I have also noticed on a number of chain-driven cars, owing to the improper adjustments of the radius rods, that the rear axle does not set square or at right angles to the center of the car, which causes friction and undue strains upon the bearings, sprockets, chains, as well as excessive wear on the tires.

"While we have a few of these discrepancies in the bevel gear drive, it must be conceded that all the gears and other parts of the construction are properly protected from dust and dirt, and that at all times it has a sufficient amount of lubrication, which not only adds to the life of the parts, but reduces the friction, especially when working under excessive strains. Quite a large number, if not all, of these imperfections have been overcome in the unit transmission system, and the last, but not least, important feature of this system is the silence with which it transmits the power. I should say that it is physically impossible to obtain as quiet a running car with either the side chain drive or with a car equipped with the transmission on the sub-frame and using the plain type axle, as it is with the unit system as has been herein described."



In overhauling the propeller shaft transmission, the torsion group should be carefully inspected. It is essential that the articulated and spring buffed supports for these levers be maintained in efficient and flexible condition. Should they be sprung, the resulting increased angularity of the propeller shaft joints would develop an undue amount of friction.

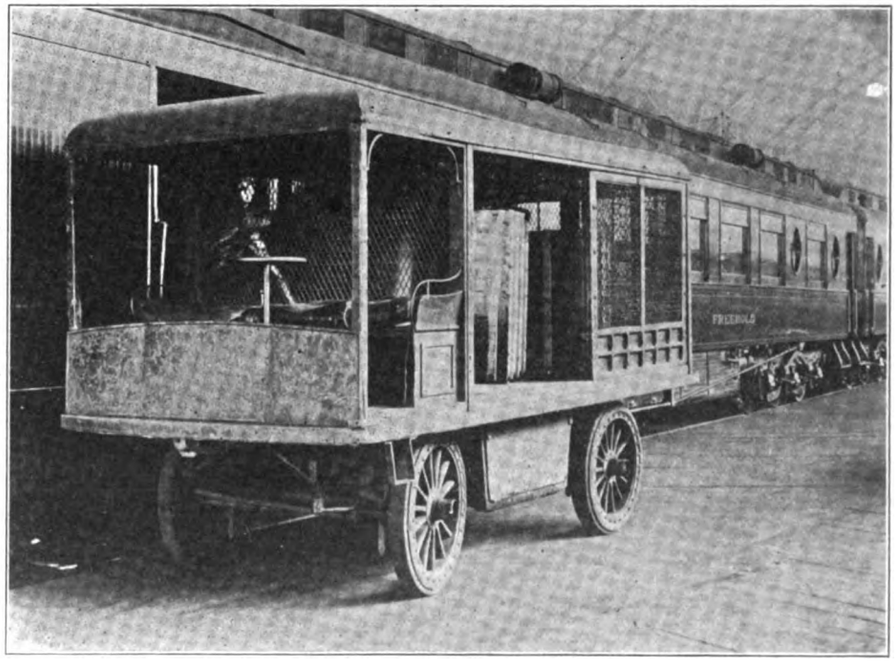
AUTOMOBILES IN RAILWAY SERVICE

Pennsylvania System Trying Out Motor Trucks for Transfer Duty at Terminals —Large Saving of Time Effected.

Introduced experimentally for the purpose of expediting the handling of freight between the stations in large cities, the Pennsylvania Railroad Co. now is utilizing automobiles between the Kensington and Shackamaxon stations in Philadelphia. The railroad company intends to try the same experiment in other large terminal cities such as Pittsburg and Baltimore, and on the results obtained from the experiments at these points will depend the decision as to making this method of freight transportation a permanent adjunct of the railroad's freight system. At the present time there is but one vehicle employed in the service.

AUTOMOBILE TRUCK FOR TRANSFERRING FREIGHT

The automobile truck, which now is in use in Philadelphia, already has saved between six and twelve hours in the handling of package freight between the stations mentioned. The machine has a capacity of five tons and is driven by a six horsepower electric motor. The truck travels about 7½ trips a day carrying 2.2 tons per trip, its daily average being about 8 miles, or 132 ton miles of duty.



Until the automobile was introduced as a possible solution of the freight transfer problem in the Kensington district, small lots of freight were sent from station to station in cars. Already the employes of the freight department have seen that the automobile service has relieved much of the freight congestion which formerly handicapped the situation, the relief being due to the possibility of movement by a direct route instead of a circuitous one, resulting in a saving of both time and delivery and the use of freight cars.

The Pennsylvania also is bringing the automobile into use in its passenger service. In Jersey City an innovation is the introduction of large automobile trucks for use in connection with the handling of baggage. These trucks are about the size of a three-horse express wagon, having platforms of 5 by 15 feet dimensions, and are so built that when they are loaded, the floor of a truck is on a level with the floor of a baggage car. Incidentally the trunks handled in this way are saved many hard knocks during their trip, as the necessity for dropping them to the station floor or to the low platform of a hand truck and later throwing them up on to a wagon or car is obviated. In moving a trunk from the car to a truck it now receives about the same handling that it would get in being shifted about inside the same car. This simplification in handling is but one of the "trunk protective" features of the trucks. Another feature is that the trucks are enclosed with wire grating sides and leather tops, which prevent the trunks from scraping against the sides of the buildings or ferries or falling during the trip across the river. The frequent traveler is likely to appreciate the importance of the change should the automobile be adopted permanently for the handling of baggage and the process of "baggage smashing" thus be eliminated.

The service to which the new automobile trucks are being put entails their making through trips between the baggage cars and the Twenty-third street station in New York City. They are loaded to their full capacity and are raised and lowered between the ferry levels on elevators.

The electric power does away with the manual labor formerly necessary to push loaded trucks up the heavy grades at the approach to the ferries at certain conditions of the tide.

In the Broad street station, Philadelphia, smaller trucks, about the size and of much the appearance of the familiar hand trucks, are used for the transportation of baggage and mail. In these trucks the electric mechanism is placed under the body of the vehicle and is operated from the handle or "tongue." So satisfactory have these automobiles proved in the baggage and mail service, that a number of them are now being built for use in the new terminal in Washington.

AUTOMOBILE TRUCK FOR HAULING BAGGAGE

PRACTICES THAT MENACE SPORT

Coler Discusses Unfair Competition and Erratic Decisions—Necessity for Uniform Rules Uniformly Enforced.

It always is somewhat difficult for me to speak of "sport" in connection with automobiling, because the utilitarian side of the motor vehicle appeals to me so strongly as to overshadow oft-times the uncertain and not infrequently undeserving element of sport, says Ernest Coler, in The Co-Operator, the Maxwell-Briscoe house organ, and yet it cannot be denied that contests have done a good deal for the automobile industry in calling public attention to the usefulness of what only a short time ago was called the new conveyance. Among such contests the endurance run has furnished the most eloquent proofs and permitted of the most far-reaching conclusions. Most readers will know that in nearly every endurance contest Maxwell cars have been winners. In a few instances they have been losers—good losers—when vicious roads, an unexpected skid or adverse circumstances of some kind or other have left a Maxwell car without an absolutely perfect score.

In making the automobile contest the subject of an article in The Co-Operator I desire to call attention to the somewhat unhealthy condition of the automobile contest and particularly of the endurance run, whose importance is too great to be threatened by the danger of having it turned into the semblance of a farce. In the early days of the endurance run it simply was a case of getting there; when the sealed-bonnet contest made its appearance the added difficulty only lent more zest to the strife and incidentally served as an excellent means to demonstrate to the general public the reliability of the motor car; when the successful completion of an endurance run was made contingent upon the rule that no adjustments whatever were to be made to the working mechanism, the frequency of perfect scores in such events only proved a further evidence of the automobile's value as a conveyance that was eminently fitted to be used by the average untrained operator.

The first requirement to be observed in any decent sport, and one that is generally heeded even in so innocent a pastime as the poker game, is honesty. But the participants in automobile contests frequently are actuated by anything but a desire to be obsolutely fair. Serious though this statement be, it is true and the fault lies not only with the managers of contests and their subordinates, but also with the manufacturers and dealers who enter cars. It is the custom, for instance, to place an observer on every car in an endurance or reliability run. The observer should be impartial, report every infraction of the rules, and subject the car to penalization, if deserved. But imagine a contest in which, as it happened not long ago, the distribution of observers was so skilfully and successfully juggled that a car entered by a well known manufacturer had for the official observer the best mechanic from his own factory, a man in his own pay and allegiance. What sort of a score could be expected from such a fraudulent combination, but a perfect one?

In a recent gasolene consumption contest Mr. C. W. Kelsey, who drove a Maxwell car, was approached by the official observer with the proposition to lend to him (the observer) a raincoat, in return for which favor he offered to permit the driver to take on a supply of gasolene sufficient to insure a fake victory. It is needless to say that the offer was declined with scorn. Mr. Kelsey prefers to win, and does win, "on the level," as every sportsman should make it his aim to do.

Two days after the last Vanderbilt cup race, in which Wagner and his Darracq won the much-coveted prize, it was discovered that the winning car was minus a differential and therefore had to be classed as a freak. Freak cars, according to the self-made and accepted rules of the managers of the race were barred from competition in the Vanderbilt cup event; yet the Frenchman had possession of the trophy, and so, as the best way out of the dilemma, the American managers simply reversed themselves by deciding that a car without a differential was no freak car, after all.

If you, gentle reader, were to take part in a contest of some kind, and if you were penalized one point simply because you had the misfortune to lose the stopper from the business end of your brandy flask—provided that this was your favorite tipple—would you not tap your index finger significantly against your forehead and look with fact-born suspicion upon the author of so assinine a decision?

This may be a somewhat far-fetched allusion, but it seems to serve as a striking illustration of the absurdity of the rulings and conditions under which some contests are decided. Some of these rules are of a most curious kind, little apt to be of assistance in disclosing anything except the peculiar mental state of the authors of the rules and the twisted view taken by them of things of which they themselves evidently possess no practical knowledge. If it had happened in the old bicycle days that a rider should be disbarred from the award in a century run or a road race simply because a spoke of the wheel had become unfastened, what would have happened? And now try to put yourself into the mental attitude of a so-called technical committee of a Pennsylvania motoring club, which decided that a car should be penalized for the loss of a tail pipe that was supposed to issue from the muffler, but didn't, because the car had been made without it, so that the car was in its original condition when it passed the expert gaze of these technical critics.

What is needed is a more uniform set of rules by which automobile contests are to governed. The Maxwell-Briscoe Motor Co. who no doubt have been the most prominent automobile concern in supporting the reliability contest, even to the extent of expending between $10,000 and $15,000 a year upon this most efficient form of advertising the road value of an automobile—are emphatic in their condemnation of the deplorable management of some recent competitions, one of the most flagrant examples of which occurred in Harrisburg, Pa., not so long ago, and partly inspired this article. I have no doubt whatever that the proper authorities will take this matter in hand shortly and if action should be delayed much longer it would raise the interesting question whether decisions in an endurance contest are to be governed by the approval or disapproval with which the judges view the curvature of the fenders, the style of the contestant's necktie, the cut of his shirt tail, or by a sportsmanlike consideration of performance and merit.

Ready Reference Handbook for Motorists.

To the novice in automobile matters who is desirous of learning just enough to enable him to run and look after his car without overburdening himself with technical knowledge, it is something of a cross to be forced to wade through a complete treatise on the subject, however well written it may be. Furthermore, few such books are adapted to ready reference use in time of need.

In "Care of Automobiles," which has just been issued by Doubleday, Page & Co., New York, Burt J. Paris has endeavored to bridge the gap existing between the makers' books of instruction and the full-fledged automobile educators, thus supplying the requirement of such an owner. He has succeeded in making a most readable little volume, which the publishers have produced in convenient size for the coat pocket, and printed without illustrations, in a clean style, quite in contrast to the formula and diagram bedecked pages of the conventional text book, and which, by the way, form its repellant feature to the layman. Subjects are indicated in a general way by sectional headings, and the matters treated are covered in a brief and sufficiently elementary manner to be of real value to the reader.

At the same time, not all the advice given is of first proof. Thus, the author suggests that a chain which has stretched beyond its normal length may be shortened by bending out every other pair of side plates. Those who have had experience in such matters, incline to the opinion that a chain which can be "sprung" in this fashion, will pull right back into its former condition, while the uneven pitch obtained by springing alternate plates, is distinctly bad. This, however, is an exception to matter which otherwise seems uniformly good.

THREE NEW IGNITION SYSTEMS

Otto Heins Explains Their Essential Features—The Latest Dual Type and Its General Simplicity.

Three new types of ignition apparatus which have been introduced by the Bosch Magneto Co., within a comparatively short time, form the subject of a paper read by Otto Heins, in Detroit, at the meeting of the Society of Automobile Engineers, last week. One which is especially noteworthy comprises a low tension magneto with synchronus distributor and magnetic plug. The features and advantages of the regular low tension system are preserved, without the drawback of the external mechanism which that system requires, while its place is taken by a magnetic interrupter, which replaces the ordinary high-tension spark plug, and is hardly larger in size.

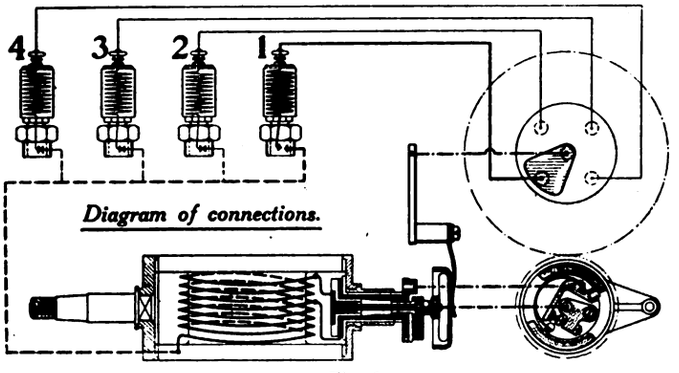

Fig. 1

"An important part of this plug is the interrupter lever," says Mr. Heins, describing the essential features of the system, "which rests on a steel knife edge, and one end of which bears on the contact piece, which is screwed into the cylinder wall in the same manner as a high tension spark plug. At the bottom of the contact piece there is an insulated, fixed stem which is magnetically divided in about the middle by means of a brass part, so that when the current passes through the coil, only the portion of the stem above the brass part can be magnetized, and as a result of this magnetization, the upper end of the interrupter lever, which directly faces the magnetized part, is attracted, the lower end simultaneously breaking contact with the contact piece, thus interrupting the current and producing a spark. In the normal position of the interrupter lever, the lower end presses against the contact piece, being kept in that position by a horseshoe-shaped spring, which passes right over the top of the stem and lies in slots in the sides thereof.

"The top of the coil is fitted wtih a contact screw to which the current from the magneto is led. This magneto generates an ordinary low-tension current and is provided with a low tension distributor distributing the current to the individual plugs, according to the number of cylinders, so that only one low-tension wire for each plug is employed."

Of the method of connection, which is illustrated in the accompanying Fig. 1, he says:

"A portion of the wiring of the armature is short-circuited by the platinum points of the interrupter, and when the circuit is interrupted, the resulting armature reaction has the effect of raising the voltage of the armature sufficiently to operate the magnetic plugs. The rotating distributor bar is adjusted in such a way that it is always in connection with one of the spark plugs at the moment when the contact breaker of the magneto interrupts the circuit, so that the circuit to the plugs is closed and they are magnetized for operation.

"The spark is advanced or retarded by rotating the timing lever, in the same manner as with a high-tension magneto, and the timing range corresponds to an angle of 50 degrees on the armature shaft. The magneto is switched off in the same manner as a high-tension magneto, by making a ground connection. This is done by small plug switches with either a single plug or with a number of plugs equal to the number of cylinders, to enable each cylinder to be switched out separately for testing purposes, from the seat while the car is in motion. As compared with mechanically-operated igniters, electro-magnetic plugs are far simpler, and they are also far more convenient, because they require no separate adjustment, as they are operated by the magneto itself."

Because of the vast amount of attention which has been paid to methods of dual ignition within the past year or two, the most recently developed product of the Bosch Magneto Co., should be of especial interest. It is a high-tension magneto, accumulator and coil combination, perfectly synchronized, and noteworthy in that the single vibrator which is used when current is being taken from the accumulators, is employed only when starting the motor. At all other times, the interruption of the primary current is accomplished by a circuit breaker on the magneto, so that the element of vibrator and coil lag is entirely done away with. The general simplicity of the layout also is a commendable feature. In reference to the system and its accessories, the authority says:

"The high-tension magneto, or the generator itself, differs from the standard rotary armature type in two respects only. In the first place, the high-tension connections are slightly altered, and, secondly, an additional contact-breaker for the battery is provided, ... so that the magneto will serve also the function of a timer for the battery, while the one high-tension distributor of the magneto is used with both the magneto and the battery current. All other details of the magneto are similar to those of the ordinary machines, and it is therefore not necessary to describe them here.

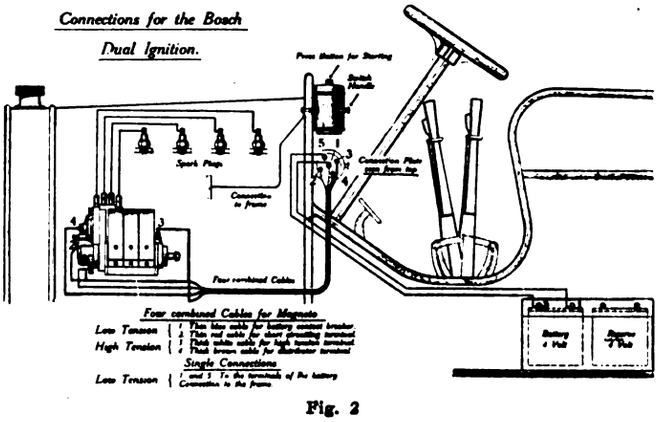

Fig. 2

"For the battery ignition a special coil is provided, with a self-contained switch and a button for bringing a magnetic vibrator into circuit when desired. These various parts are all contained in a relatively small brass case, designed to be fitted to the dashboard. . . . .

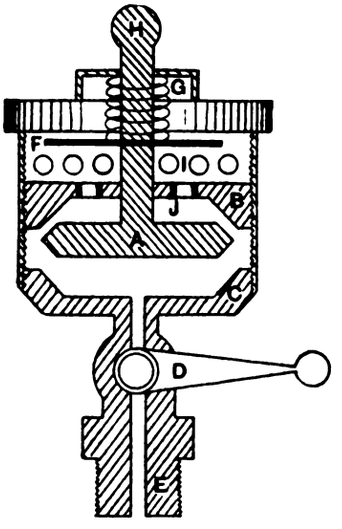
"Contrary to usual practice in vibrator coil ignition, the vibrator in this new Bosch ignition system is only brought into operation for the purpose of starting the motor from the seat. As soon as the motor is working, the vibrator is cut out and the interruption of the current is effected by mechanical means. Consequently there is no lag in the operation of the circuit interrupter, as in the ordinary vibrator coil system, thus making a synchronized system. If there is any gas in the cylinder, the motor can be started from the driver's seat by simply pressing the button. The coil is of the general form of an H armature, and not of the usual cylindrical form with concentric windings. It possesses the same amount of self-induction as the magneto armature, and while running the engine the two systems are absolutely synchronized, and no difference is apparent in the speed of the engine, whether the magneto or the battery is used.

Digitized by Google

"The trembler is only used at the moment of starting. The button switch for bringing it into circuit is fitted in the lid of the case in such a manner as to render it quite waterproof. In order to eliminate all long connections between the switch and the coil, the switch is directly combined with the brass housing of the coil, the short contact studs being well insulated from each other in the base of the housing. The connections are made by small segments in the bottom plate of the coil frame, the entire coil being moved towards the left or the right to effect the change-over. The switch handle projects through a circular slot in the housing and locks in three positions by a spring, the positions being designated respectively, as 'Magneto,' 'Off,' and 'Battery.' The combination is very compact and can easily be inspected by unscrewing the switch handle and removing the lid, exposing the components of the switch.

"The casing or housing being watertight and made of metal, prevents the coil being affected by atmospheric conditions. No wood is used in the construction. The connections between the dashboard and magneto, as shown in Fig. 2, are made by one quadruple cable, which contains the two high-tension wires and the two low-tension wires. Standard magnetos can be adapted to this dual system by only small alterations."

As a result of the growing demand for cars of low and medium power equipped with high tension ignition, a new development of this type has been produced, which is intended for use upon motors up to 15 horsepower and of simple construction.



"The interrupter," says Mr. Heins, "is similar to the standard interrupter, but the distributor disc is of novel design and can be taken off with a jerk by pressing the spring on both sides. To simplify the ignition device, the magneto is generally furnished without any timing device. As these magnetos will generally be used on small cars driven by persons with no special technical skill, the absence of a timing device has the advantage that the engine cannot be abused by incorrect timing. The magneto, however, can be readily supplied with a timing device.

"On certain engines, particularly two-cycle and racing engines, an unusually large timing range is required. This necessitates the shifting of the magneto armature with respect to the driving shaft, which can be accomplished by a novel coupling device brought out by the author's firm. This coupling device can be attached to practically any type of our magnetos. It consists principally of two rotary sleeves. . . . . one fitting into the other, both provided with helical slots running in opposite directions, so that by moving the collar which carries pins which extend into the above mentioned slots, an angular movement of these sleeves relative to each other up to 60 degrees is obtainable."

AUTOMATIC COMPRESSION RELEASE

Simple Device for Relieving the Labor of Cranking—Its Action in Preventing the Dilution of Charges.

Generally speaking the automobile designer is content with providing pet-cocks in the cylinders for relieving compression in the motor when starting. In a few instances, means is provided for automatically releasing compression by a partial opening of the exhaust valves, the effect being secured by the act of engaging the starting crank itself. While occasionally provision is made for opening all of the pet cocks simultaneously by means of a special button or handle placed in the front of the radiator. That some automatic compression releasing device is possible as well as desirable, is perfectly evident.

Such a device was described recently in the Motor World as consisting of a cock of the ordinary type, except for a spring retained valve opening outward, and set to release at a predetermined pressure. The effect of this was to retain a certain amount of compression in the cylinder, and also to prevent any regurgitation through the valve as occurs with the ordinary pet cock, thus diluting the charge.

Somewhat similar in intent, but embodying one or two improvements, is a valve described in a recent issue of the Autocar, as here illustrated. Instead of a simple check valve with adjustable spring tension, this device has a double-seated valve, which is intended to close automatically whenever an explosion is secured, at the same time permitting the release of compression at any predetermined pressure when the motor is turned over by hand.

Its construction is perfectly evident. In order to put the device into operation the stop cock, D, must be opened. When this has been done and the motor is cranked slowly, the force of compression is sufficient to unseat the valve, A, from the seat, C, against the resistance of the spring, G. The spring is set ordinarily, to release at about 8 pounds per square inch. The gas at once escapes through the relief holes, I-J. The force required to turn over the motor is thus materially relieved, while a certain amount of compression is retained, and the automatic action of the valve prevents any induction of pure air from outside to dilute the charge.

When the first charge is fired, the force of the explosion at once drives the valve, A, the full length of its travel until it seats in the shoulder, B, thus practically sealing the cylinder. A very slight leak of gas is permitted during the travel of the valve, but except for this, the motor runs on practically the full force of the explosion. When the engine is running in this way, it is said that there is practically no clatter from the valves, despite their automatic action, and the power of the motor is practically unimpaired. After the cycle is taken up in the regular way, however, the cock, D, is closed, thus establishing the full performance of the motor. By lifting the knob, H, it is possible to inject fuel through the valve into the cylinder, as with the ordinary pet cock. The device thus in no way interferes with the working of the motor under ordinary circumstances, except for the very slight loss of power occasioned by the escape of a small amount of gas during the time between the unseating of the valve and its second closure of the cylinder at the end of its travel. Closing the stop cock in the base, prevents even this loss, and leaves the motor in perfectly normal condition.

To Keep Dust Out of Oil Reservoir.

As it is not always possible to obtain a strainer funnel at the time and place that the contents of the lubricating reservoir is being replenished, and as strainer funnels, even the very small ones, soon get into an oily condition which makes them undesirable to carry as part of the equipment of the car, some simple method should be employed by which the oil reservoir can be kept free of dirt or other foreign substances. A very simple arrangement to accomplish the purpose consists of nothing more than a piece of wire gauge rolled into tubular form of the diameter sufficiently small to permit of its being inserted in the filler hole of the oil reservoir. A ring should be soldered around the top of the gauze tube so that it will not enter too far into the tank. A bottom is soldered to the tube and when the completed screen once is inserted in the filled hole it remains there permanently, excepting when it becomes necessary to remove it for cleaning purposes. Such an arrangement will catch and retain pieces of waste, grit and other substances that would cause annoyance, if not indeed serious trouble should they find their way into the cylinder or come in contact with journals or wrist pins.

1909 FOUR-CYLINDER

Stevens-Duryea

MODEL X

In bringing out this new model we do not in any way retract any claims that we have made for the six-cylinder car which we are firmly convinced is the highest type of automobile construction. In response to a demand for a larger and roomier car than our twenty horsepower four-cylinder Model R, and more moderate in price than our Light Six, we have produced the Model X. This model supplies a demand for a four-cylinder car a little larger and more powerful than the Model R, which has been discontinued. The owner of the Model X can feel that the well-known features of the Model R are enbodied in his car, together with the advantages of more room and power. In brief, the Model X is an enlargement and refinement of the Model R, representing the most advanced ideas in automobile designs, together with Stevens-Duryea construction and workmanship, which have been proven absolutely correct.

The Unit Power Plant
AND
Three-Point Support

This construction, which has made the name "Stevens-Duryea" synonymous with motor car efficiency, is retained. Stevens-Duryea cars were built on correct principles in the beginning, and at no time have any radical changes been made in their design.

4¾-INCH BORE.	TIRES, 34 x 4 INCHES.
4½-INCH STROKE.	WEIGHT, 2,650 POUNDS.

For detailed specifications send for catalog.

Price	**$2,750.00**
Folding Top with Side Curtains, Storm Front, Celluloid Windows, and Slip Cover, extra	$150.00
Magneto, extra	200.00
Chassis	2,400.00

THREE POINT SUPPORT — UNIT POWER PLANT

MAY ESCAPE BETWEEN LAWS

Odd Point Raised in Rhode Island Prosecution—Immunity Claimed Through Repeal of Old Statute.

Somewhat involved is the legal issue that has arisen under the new Rhode Island law in connection with the case of Forrest G. Wilcox of Providence. J. Jerome Hahn, attorney for Mr. Forrest, has brought before the Superior Court the contention that the new automobile law prevents all prosecutions of automobile cases except those brought under the new law. The action taken in the case of the State vs. Forrest G. Wilcox on appeal asks for the dismissal of the case and the quashing of the complaint and warrant on the ground that the chapter of the Public Laws under which the complaint and warrant were brought alleging violation of its provisions was repealed by the Legislature at its last session and that no law now exists under which he can be tried on the charges set forth. The contention of Attorney Hahn is as follows:

"The defendant in the above entitled cause moves that it be dismissed and the complaint and warrant therein be quashed, because he says:

"First, That chapter 1157 of the Public Laws, passed April 13, 1904, under which said complaint and warrant was brought, charging him with the violation of its provisions as set forth in said complaint and warrant, was repealed by chapter 1592 of the Public Laws passed on the 26th day of May A. D. 1908.

Second. That no law now exists under which he can be tried, convicted and sentenced on the charge made and set forth in said complaint and warrant against him.

"Third. That no provision or provisions now exists in law whereby he can be sentenced for the violation of any of the provisions of said chapter 1157 of the Public Laws.

"Fourth. That no law exists whereby he can be held on the charges contained in said complaint and warrant."

The complaint against Mr. Wilcox alleges that May 28, 1908, Forrest G. Wilcox of Providence "did ride and drive an automobile faster than a common traveling pace on one of the said streetsof said Providence, to wit, Broad street, against the statute and the peace and dignity of the State."

It is held that by legislation automobiles have been placed in a special class of vehicles and that, therefore, a complaint in such general terms as "faster than a common traveling pace" is not specific enough to hold.

Cop's Legs as a Speedometer.

That speedometers and stop watches no longer are required in timing speeding motorists—at least in New York City, is the conclusion to be drawn from the testimony of Jost Ruth, a policeman who on Sunday last arrested Michael Coogan, a chauffeur, whom he charged with driving a car faster than 20 miles an hour through the streets of the city. When Coogan's case was heard in court, Officer Ruth testified that he had not timed the defendant by any of the usual methods employed by the police, but merely had run after him. The policeman swore that he could run a block in 10 seconds flat and that he had had to run two blocks before he jumped into another automobile and captured the speeding chauffeur. He based his complaint on the rate of speed at which he had run the two blocks. Ruth's method of timing was not approved by the court, for Coogan was discharged.

New York Registration Shows Decline.

Registration figures at the office of the Secretary of State at Albany show a falling off in the number of automobiles registered in the State of New York for the first six months of the current year. Up to July 1, 1907, there were 8,225 registrations, while the figures for the first six months of 1908 show a decrease of about 200.

MICHELIN

FRANCE, ENGLAND, ITALY, AMERICA.

Whenever Michelin tires are compared with any other makes for good wearing service, reliability, durability and economy, the lead of Michelin's is always emphasized, and here are some reasons why:

In 1895 Michelin made the first successful automobile tires ever constructed. Our entire time and attention ever since have been devoted to building tires and tubes only, and not divided among various lines of rubber products.

Michelin tire quality proves that concentration counts, by winning every important contest in Europe and America in which they participate. Michelins get harder usage in these events than you can ever give them, and they invariably withstand it successfully.

Don't you think we know something about tires when you consider that to September last we had made 1,180,830, or tires enough to equip 26,837 automobiles, each and every year since 1895?

In spite of the fact that Michelin tires cost a trifle more than others, more than half the cars in Europe are equipped with them, because the car owners can get no other tires to give the Michelin's economy and satisfaction of service.

Isn't it about time you equipped some of YOUR cars with Michelin's to show your customers that in EVERY particular your car is the BEST in its price and class?

ABOUT THE ROTARY PRINCIPLE

Why Its Application in Engine Design Has not Proved a Commercial Success—Its Alluring Possibilities.

Every student of the steam or gas engine has, in all likelihood, fallen victim to the lure of the rotary motor at one time or another. Usually the particular arrangement of parts which attracts his attention is presented in a novel form which appears to be so very "new" as to promise as great things for the future as its inventor is certain it holds. That the rotary engine, by which is meant the type of motor in which the usual piston and connecting rod motion is dispensed with in favor of some other mechanism, is actually by no means a novelty, is explained by Professor C. Smith in the Autocar.

"The rotary engine occupies a position unique in the history of invention," he remarks. "For over 50 years it has received the attention of inventors, and no efficient engine has yet been devised. It is remarkable that a type of apparatus which has met with so little success should continue to be the object of such care and thought. . . . . The idea of the rotary engine is to arrange the piston or part acted on by power, so that a motion of rotation is communicated directly to the shaft, without the interposition of the familiar crank and connecting rod. The ordinary steam engine mechanism is admittedly a source of considerable loss of power, but not so great as some inventors seem to think. The loss is a friction loss, which generally has its counterpart in the rotary engine; the obliquity of the connecting rod produces a variation of torque in the crankshaft, but the variation is compensated, when necessary, by a flywheel.

"The obliquity is not the principal cause of any loss peculiar to the reciprocating engine; vibration and alternating stresses are the chief objections.

"The revolving cylinder engine must not be confused with the rotary engine. For the former there appears to be some future. Considerable attention is being paid to the details of its design. . . . . The air-cooling effect on the cylinder is admirable. A result of the rotary cylinders is that there is a flywheel action due to them, hence the extra weight of a fly wheel is saved. . . . .

"The steam turbine, though certainly a 'rotary' engine, is usually considered a thing apart, and is not classed among the machines known as rotary engines. With these latter there is always a part—an abutment—corresponding to the cylinder head of an ordinary engine, and against which the steam or petrol gas expands. The piston usually consists of a vane or block of variable shape projecting radially from the periphery of a drum mounted on the engine shaft. The whole is enclosed in a casing, there being an annular space between the casing and the drum. This space corresponds with the cylinder of the ordinary engine. On pressure being admitted, the piston block or vane is forced away from the abutment, and travels round in the annular space, thereby giving a motion of rotation to the shaft. It is clear that the power can force the piston round for a complete revolution, after which the piston will be again adjacent to the abutment, only now it will be behind it instead of in front of it. The piston must therefore, be got past the abutment in order that the rotation may be continued, and this operation the inventor accomplishes in an astonishing variety of ways.

"In one type of engine the abutment is caused to slide radially outwards out of the way at the right instant by a cam or other mechanism worked from the engine shaft. As soon as the piston block has passed the abutment is brought back into place again, steam is admitted as before, and the motion is continued. . . . . In another type of rotary engine the abutment is made to rotate. It takes the form of an equal armed cross or star, mounted in such a way that the arms project successively into the annular cylinder. The piston block strikes the arm which for the time being is acting as the cylinder head, and causes the abutment to rotate about its spindle. The arm in front of the piston moves out of the way, and the next arm comes down behind the piston to act in the function as a cylinder head for the next stroke, and so on. A great number of modifications have been suggested, especially in the shape of the abutment and in the manner of its rotation. Sometimes it is rotated by cams on the shaft, and very frequently it is made to act as cut off valve in addition. . . . . There is yet another common form of engine possessing a movable abutment. This time the abutment is actually hinged at one end to the outer casing, while the other end bears upon the internal drum from which the piston block projects. As the block comes round it pushes the hinged part more or less gently out of the way.

"In all the types considered up to the present the abutment is withdrawn at the proper instant from the approximately circular cylinder, but in another very wide class the abutment is fixed, and the piston block itself is caused to get out of the way at the right instant. Evidently the piston block cannot in such cases be a fixture on the internal drum. The most obvious way of effecting its disappearance when required is to arrange for it to slide into the drum just as in the other case the abutment slid outwards. The piston vane is forced inwards by the inclined faces of the abutments or by suitable cam gear, and springs are generally set in the slot in the drum to force the vane outwards during the ordinary part of the revolution.

"These are the main types of rotary engines, though many peculiar constructions which do not come under these heads have been proposed from time to time. The so-called spherical engine, for instance, is perhaps one of the most ingenious pieces of mechanism ever devised for the development of power. Description is practically impossible without reference to models or drawings. It will suffice to say that the steam 'cylinders' usually take the shape of segments of oranges, and that a disc wobbles about in them in a wonderful manner. The motion of the disc in some forms of the engine is exactly reproduced in the motion of the middle part or cross of the coupling known as a Hook's joint.

"The idea of a rotary engine is attractive at first sight, and one can understand the enthusiasm of the inventor whose engine, according to his expectations faithfully reported by non-technical writers in the daily press, is to revolutionize the industry in some or all of its branches. But it needs only a moment's consideration of the mechanical difficulties in the way to realize why these engines have so far been commercial failures, and why they are forever likely to remain so. The wear and tear at the abutments and piston parts is enormous, and is increased by any mechanical constraint designed to remove the uncertainty of action of these parts. Rotated at low speeds, each piece of mechanism will very probably give satisfaction as a pump or blower, but in a prime mover we must have a fair speed, and little wear and tear as well as a low steam consumption. . . . . In spite of all this, the flood of invention in this direction increases year by year. The present tendency is to simplify the parts and modify the engines for working with petrol, etc., but with the steam turbine giving such satisfaction and the gas turbine looming ahead it seems a waste of ability to seek to introduce rotary engines."

How to Test the Manometer.

Whatever advantages are to be derived from the use of the manometer, or gauge for determining the rate of water circulation in the cooling system, are set at naught if the gauge fails to register accurately. This may occur when the tubing by which it is connected to the water piping leaks, or is badly kinked at some point, when the tubing is clogged, or when there is some internal flaw in the device itself. A simple test which may be employed when the correct indications for any given speeds are known, is to apply a revolution counter to the end of one of the cam shafts, running the motor at various speeds, and simultaneously observing the indications of the gauge. If the latter correspond to double the speed of the sam shafts, they are sensibly correct. If not the device should be adjusted properly, where adjustment is possible, or else a new dial made, providing it is not possible to effect the desired result by the easier method of shifting the old one.

"DOING OVER" THE RUNNING PARTS

Practical Suggestions for the Preparation of New Surfaces—Materials and Methods for the Finish.

It is easy enough to order a much used and seedy looking car to be "done over," but as a rule the owner has small conception of the amount of labor and pains which must be involved in doing a really creditable job under the circumstances, while many a professional painter is more or less at a loss to know how to set about it to get the results which are expected in such cases. In respect to the treatment of the most difficult part of the undertaking, namely the renewal of the running gear, the Carriage Monthly furnishes some advice.

"The cracked and fissured automobile body is concededly a difficult bit of work to make really presentable short of burning off the old paint and resurfacing anew, but the ring-cracked and alligatored running parts are quite on a par with the body of like condition in the matter of downright hard work and good skill in bringing up to a satisfying finish," says this authority. "The first and most important move following the washing of the parts, cleaning off the grease, etc., is to scrape away all the fractures, uproot the splinters and knife out the gouges in which shivers of wood prick up to smite the hand of the workman. This, of course, can best be done with steel scrapers, sharpened to a keen edge on one side, with wood handles affixed. We have for this purpose often used mowing machine knives, and, in fact, they make most excellent scrapers, although somewhat tiresome to handle. In city shops, this scraping and sandpapering of the running parts is accounted a particularly nice sort of work. Usually some one unusually interested in this class of work is put in charge of it and becomes expert in it.

"At this stage, it fairly goes without saying, the whole issue of the case depends. As one of the best foremen painters of Manhattan recently said, 'Both the character and durability of the finish depend more upon this primary surfacing than upon any other single operation.' Face and back of felloes, front face of spokes, sharp edges on hubs, if any exist, face of axle bed, side bars, etc., are parts of the surface demanding particular attention. All such spaces, and, indeed, all spaces, need to be worked down until the wood fiber lays low and clean and perfectly free from any stringy substances. And of the sandpapering it need merely be said that this should be carefully and skilfully done. Everything of a loose or shelly nature should be torn away and removed under this scraping and sandpapering attack, so that at the termination of it nothing remains which can disturb or unseat this structure of pigment built upon it. Thorough scraping and sandpapering goes far towards removing the necessity of much puttying of the running parts, a fact in itself important to consider.

"The surface being fitly prepared to coat upon the next step consists of either using for a first coating some one of the many well-accredited running parts, surfacers, or straight lead compounds made up in the shop. And in respect to the shop-prepared pigments, it may be said that for impalpable fineness of atoms, softness of texture, and capacity for penetrating the crevices, and surfacing up rich and velvety under the sandpaper, and for general excellence as a supporting pigment, nothing equals white lead of approved quality. For this initial coating make it to a camel's hair brush power consistency in one part pure, raw linseed oil and three parts turpentine. Permit this coat to dry 72 hours, and then over the coarse eaty patches of surface glaze with a quick-drying putty cut to the desired consistency with turpentine, using both an ordinary putty knife and a full elastic French scraping knife. This glazing putty will dry sleek and hard, and sandpaper to powder, in 36 hours. Then with the quick-drying putty fill smoothly all cavities and gouges. After another 36 hours sandpaper the parts uniformly, without cutting through, and coat with a second application of lead made by the addition of one part oil to five parts turpentine. For a strictly high-class job, add, after again sandpapering a third coat of lead, carrying one part oil to ten parts turpentine."

What Determines the Motor's Speed.

Curiously enough, one of the most puzzling questions in connection with the operation of the gas engines, is that relating to its speed. Just why one engine should develop its best performance at a rate of revolution nearly twice as great as that required for another affording perhaps the same horsepower, is difficult to understand, even when the sequence of the cycle itself, is well known. The whole matter reverts to the original design of the motor. Just as a man with long legs, takes fewer steps and longer steps than a man with short legs, when both are of the same weight and traveling at the same speed, so two engines of different design though producing the same power output, may do so at different rates of travel. Just how the differences are brought about from which these effects are developed, is entirely a different matter. The analogy is a simple and helpful one to remember, however. In this connection it should be noted that the high speed engine is designed with extremely light working parts, perfectly balanced; and that its proper working demands a great number of relatively light impulses in order to produce its output. The slow-speed motor on the other hand, may be less accurately balanced, but requires far heavier working parts because of the relatively heavy explosion pressures with which it deals.

ADVANCED TYPE OF FIRE FIGHTER

Hollywood, Cal., Gets the Latest Ideas in Its Automobile Chemical Engine—Features of Construction.

While automobile fire engines in various forms have come into use in many cities throughout the United States, during the past year, what may be termed the most advanced type of automobile chamical fire-fighting apparatus recently has been purchased by the city of Hollywood, Cal. The vehicle is comprised of a well designed body, mounted on a special Tourist chassis. The motor is of 4 cylinders, developing 50 horsepower; selective type transmission, and two ignition systems.

The fire fighting equipment consists of a 40-gallon chemical tank of heavy copper placed crosswise on car under the driver's seat; 100 feet of ¾-inch four-ply chemical hose coupled to automatic reel with ¾-inch Larkin nozzle; two 3-gallon regulation fire extinguishers, 2½-inch hydrant connection for 2½-inch fire hose; four 9-foot ladders specially fitted to connect into one 36-foot ladder; a full complement of lanterns, crowbars, pickaxes, plaster hooks, etc.

The main body of the car is of steel, designed to carry 800 feet of 2½-inch fire hose. There are two alarm bells on the wagon. One is a large pivoted fire bell which can be operated either automatically or by a man on the footboard. The other is a 12-inch electric gong on the dash which is rung by a switch connected with the storage battery.

The lighting system consists of two large gas headlights and a central gas search light, the latter so arranged that it can be turned back, illuminating the entire outfit when car is at stand still.

The weight of the outfit, with tanks filled and including 800 feet of two and one-half inch hose, driver and five men, is 6,000 pounds. The lightest steam fire engine, weigh about 7,850 pounds and some of the heavy types, now in use weigh over 10,000 pounds. Its speed on the level is 45 to 50 miles per hour; it is geared to negotiate almost any grade.

The car will be housed at Hollywood in a specially designed building wherein the car rests upon an inclined plane facing the door. Upon alarm, the driver from the seat, releases chock block, opens the throttle and the car by descending the incline, starts the motor.

Adjusting Steering Gear for Lost Motion.

In adjusting the steering gear for lost motion, care should be observed, lest the parts be set so close as to bind. After completing adjustment, the gear should be tried through its entire "lock" to make sure that the alignment is perfect. If not, binding will occur.

The Week's Patents.

885,886. Hydrocarbon Gas Generator. Olva D. Sumner, Chicago, Ill., assignor to Acorn Brass Manufacturing Company, Chicago, Ill. Filed May 28, 1906. Serial No. 319,160.

1. In a gas generator, the combination of a continuously ascending generator coil, a member supporting the lower end of said coil and having a liquid fuel receiving chamber provided with independent inlet and discharge valves, said discharge valve supplying fuel to said generator, a mixing chamber at a higher level than said coil and receiving the hydro-carbon vapor therefrom, a burner beneath said generator and a supply pipe connecting said mixing chamber with said burner.

885,888. Concave Vehicle Tire. Arthur G. Thomson, San Francisco, Cal. Filed Oct. 29, 1906. Serial No. 341,079.

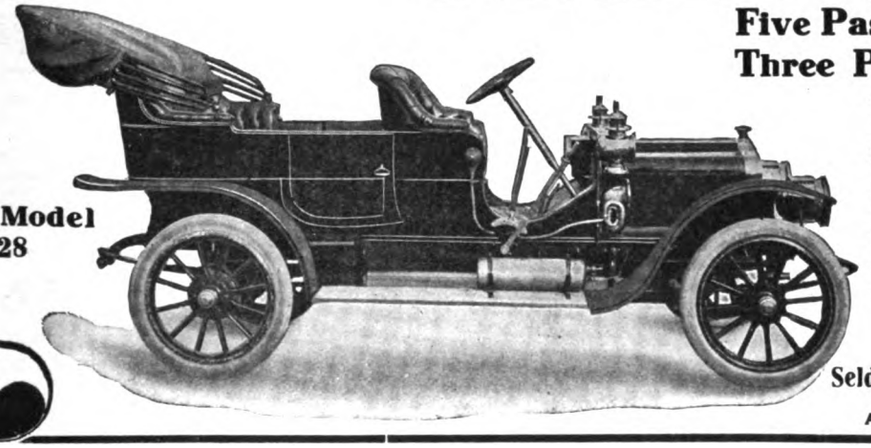
1. A wheel tire composed of a plurality of separable independent counterpart sections, each section comprising a body having a tongue projecting from one edge thereof, and a tongue of equal length but of less thickness projecting from the opposite edge, the said tongues constituting a part of the sides of the tire with the end of one tongue at a reverse incline to the end of the other tongue.

885,894. Ignition System for Explosion Engines. Richard Varley, Englewood, N. J., assignor to The Autocoil Company, a Corporation of New Jersey. Filed Nov. 17, 1906. Serial No. 343,833.

1. In an ignition system for explosion engines, a shaft having a sleeve angularly adjustable thereon, a plurality of rollers carried by said sleeve, and metallic conductors concentric with said shaft in the path of said rollers, certain of said conductors being connected into the primary circuits of a plurality of induction coils to periodically interrupt such circuits when the engine is running and centrifugal means co-operating with the remaining conductor to permanently interrupt the circuits when the engine is at rest.

885,921. Gas Engine. Chester Griswold and Sylvester G. Averill, New York, N. Y. Filed Dec. 21, 1906. Serial No. 348,863.

1. The combination of two gas engine cylinders and, associated with each cylinder, a piston and a compressed air chamber in the cylinder base receiving said piston, a crank shaft common to both pistons passing through said compressed air chambers and having its crank in one chamber set 180 degrees distant from the crank in the other chamber, an air inlet valve in each cylinder head, ducts connecting the said air chamber associated with each cylinder with the air inlet valve of the other cylinder and means actuated by said crank shaft for operating said air inlet valves.



885,938. Friction Clutch. Frank Maxant. Allegheny, Pa. Filed April 25, 1907. Serial No. 370,159.

1. In a friction clutch, the combination with a driving shaft and a flanged pulley thereon, of a driven shaft provided with a circular carrying frame, pairs of levers pivotally mounted for operation in said frame and provided with gripping shoes engaging the inner and outer sides of the flange of the driving pulley, a pivotally mounted actuating lever having integral oppositely disposed arms connected by links to the terminals of said levers and provided with a backwardly extending arm having a bearing roller, and an actuating cone slidingly mounted on the driven shaft and arranged to engage said roller, substantially as set forth.

885,940. Steering Gear for Automobiles. Grove E. Miller. West Detroit, Mich. Filed May 18, 1907. Serial No. 374,361.

1. In a steering gear, the combination of a driving screw member, a driven screw member, a clutch connection between said members, nuts mounted on said screw members, a bearing block arranged between said nuts, a rock shaft connected with said block and means for compressing said block between said nuts.

THE SELDEN CAR

Five Passenger Touring Car $2000
Three Passenger Runabout $2000

AN ATTRACTIVE CAR AT AN ATTRACTIVE PRICE

SPECIFICATIONS—Engine, 4 cylinders, 4¼x4½, 28-30 brake horsepower. Transmission, 3 speeds forward and reverse, selective, Timken bearings. Wheel base, 109 inches; tread, standard; clutch, cone leather. Body, sheet metal, straight line type, roomy and comfortable. Tires, 32x3½, quick detachable; make optional. Frame, pressed steel, 4¾ inches deep. Front axle, single I-beam drop forging, ball bearings. Rear axle, bevel gear drive, enclosed type, roller bearings. Ignition, synchronized jump spark. Weight, empty, 2,200 lbs. (actual, not catalogue).

Nuts That Require Tightening After considerable use the bolts holding the sprocket rings to the driving wheels of chain driven cars tend to become loosened in the spokes. Hence, when overhauling an old car, it is well to tighten the nuts which hold them in place, riveting over the ends for the sake of security. In doing this care should be taken not to throw the sprocket out of line.—From "Motor World," August 8, '07.

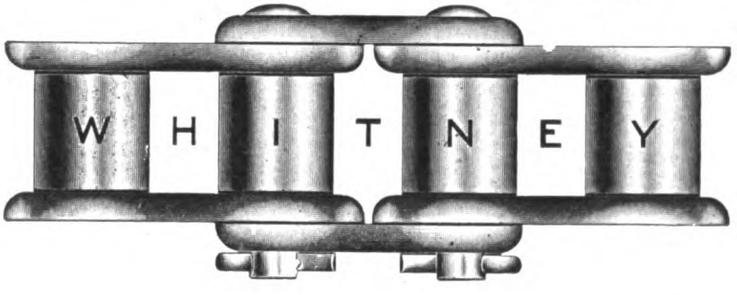
NEW "WHITNEY" CHAIN BELT

For Cooling Fans, Oiling Devices, Motorcycles, Etc.



If you are not taking advantage of the Woodruff Patent System of Keying it will pay you to investigate.

Better results and a great saving in cost.

We carry 95 regular sizes of Keys and Cutters in stock for immediate delivery.

"Whitney" Patent Cotter Detachable Roller Chains

Made a fine record in the Briarcliff Road Race.

New York City, May 2, 1908.

THE WHITNEY MFG. COMPANY, Hartford, Conn.

Gentlemen—The uniform strength of an automobile driving chain is one of the important requisites in a speed contest.

The "Whitney" Chains which formed a part of the equipment on our three "Stearns" Cars in the recent Briarcliff Stock Car Road Race, showed their superiority by coming through this exceptionally difficult contest without the slightest evidence of the terrific strain which they had undergone. Our "Stearns" Cars made an exceptional showing in this race, and we attribute our success in no small degree to the entire absence of chain trouble.

Our experience in previous contests has taught us that a faulty chain can cause a lot of trouble.

We therefore take this opportunity to express the satisfaction which we feel at the manner in which "Whitney" Chains demonstrated their worth.

Yours very truly,

WYCKOFF, CHURCH & PARTRIDGE,
By C. F. Wyckoff, President.

THE WHITNEY MANUFACTURING COMPANY, Hartford, Conn.

The Severest Tests

have demonstrated time and time again that the principles employed in

Timken Roller Bearings

are the only correct ones that insure perfect transmission of all power to traction use, eliminating both friction load and end thrust.

A Stoddard Dayton Stock Car equipped complete with **Timken Roller Bearings** finished April 12th, a ten-day century run, 1,000 miles over the roughest roads with all adjustments sealed, something impossible for a car equipped with the ordinary type of bearings to perform. This car, as do all cars of the **Stoddard Dayton** make, carries a full equipment of **Timken Roller Bearings,** as tests made under the most adverse and severe conditions have proven them an economical factor in the saving in wear and tear from strain alone.

And these are some of the reasons why more than **65 per cent.** of all the makers of high grade American Automobiles and over **90 per cent.** of the Commercial Truck builders are now using them.

Are you? If not, won't you let us give you some figures that prove. These are yours for the asking.

The Timken Roller Bearing Axle Company, Canton, Ohio

1909 FOUR-CYLINDER

Stevens-Duryea

MODEL X

In bringing out this new model we do not in any way retract any claims that we have made for the six-cylinder car which we are firmly convinced is the highest type of automobile construction. In response to a demand for a larger and roomier car than our twenty horsepower four-cylinder Model R, and more moderate in price than our Light Six, we have produced the Model X. This model supplies a demand for a four-cylinder car a little larger and more powerful than the Model R, which has been discontinued. The owner of the Model X can feel that the well-known features of the Model R are embodied in his car, together with the advantages of more room and power. In brief, the Model X is an enlargement and refinement of the Model R, representing the most advanced ideas in automobile designs, together with Stevens-Duryea construction and workmanship, which have been proven absolutely correct.

The Unit Power Plant
AND
Three-Point Support

This construction, which has made the name "Stevens-Duryea" synonymous with motor car efficiency, is retained. Stevens-Duryea cars were built on correct principles in the beginning, and at no time have any radical changes been made in their design.

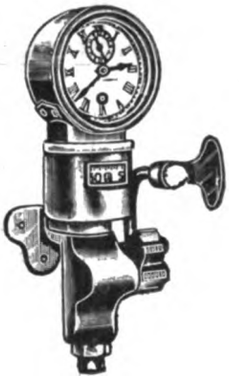
Agents in all large cities.

The Auto-Meter—Is Believed

Every big motor event that has taken place in the past three or four years has seen more Auto-Meters in evidence than all other makes of speed indicators combined.

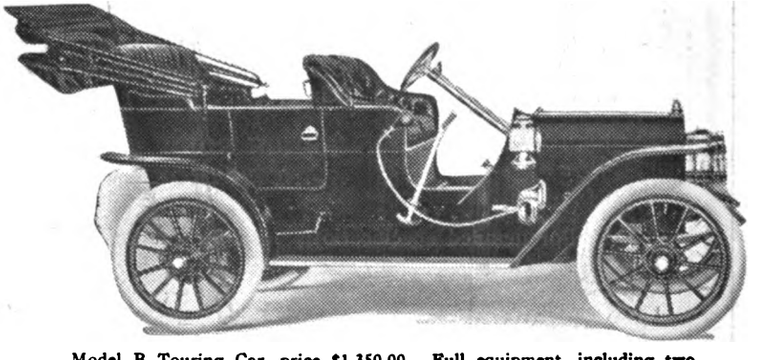
In the Glidden Tours the number of Auto-Meters used by contestants doubled and tripled all other makes put together.



In the New York-Paris Race the only speed indicator is a Warner on the Thomas car.

Nearly all the automobile manufacturers of the country use the Warner to test out their cars before they leave the factory.

Two of the most successful makers are including the Warner as part of their regular equipment.



Aren't these facts rather significant—don't they mean anything to you?

Send for our new book, "The Final Truth About Speed Indicators."

Large Sales

make it possible for us to import THE CELEBRATED BRAMPTON CHAINS from ENGLAND (paying freight and duty), and sell them at the same price at which the several other automobile chains are sold to manufacturers, jobbers, dealers and users.

THE BRAMPTON MOTOR CHAIN

All side plates on both sides on the Brampton Chain are stamped "BRAMPTON."

LARGE SALES and SMALL PROFIT with thousands of satisfied customers is our best advertisement.

THE BRAMPTON CHAIN is made of helf-hardening Steel; the strongest Chain in the World. All parts polished; fits sprockets (that are properly cut) without friction.

Some of the other chains may look like THE CELEBRATED BRAMPTON CHAIN because some of the other chain makers began to copy the design and shape of the BRAMPTON CHAIN links in 1904. They have improved somewhat on their copied design from time to time until these chains now look more like the BRAMPTON CHAIN than ever before. These chains somewhat resemble the BRAMPTON in appearance, but the manufacturers of such chains have been unable to copy the material—self-hardening steel.

NO CHANGE IN THE BRAMPTON

There has been no change in the design, construction, material or finish of the BRAMPTON MOTOR CHAIN in the past ten years.—"ENUF SED."

PRICE

The price being equal, it's presumable you want the best, and full value for your money. In such cases, the BRAMPTON FILLS THE BILL, and the prices are the same to manufacturers, jobbers, dealers and consumers as any other chain of equal size—as follows:

CHAINS TO FIT AMERICAN CARS

1 x ⅜ x 9-16—1 x ½ x ⅝—1 x ½ x 9-16 roller ..... $1.00 per foot.
1 x ⅝ x ⅝ roller ..... 1.17 "
1¼ x ½ x ⅝—1¼ x ⅝ x ⅝—1¼ x ⅝ x ¾ roller ..... 1.25 "

We also carry in stock the BRAMPTON CHAINS to fit Foreign Cars—Mercedes, Panhard, Martini, Fiat, etc.

Your 1908 Car

You can have the new car that you order fitted with the CELEBRATED BRAMPTON CHAIN if you order it that way. No extra cost to either you or the manufacturer. All standard sizes in stock to fit American and Foreign Cars at the same price as the other chains.

SPECIAL CHAINS TO FIT THE INDIAN MOTORCYCLE.

Agents wanted in unoccupied territory. Catalog on request.

We are Sole American Agents for BRAMPTON CHAINS, and they cannot be bought from anyone else except through our Agents.

Pan-American Automobile Body Polish

Pan-American Polish was awarded the Bronze Medal at the Louisiana Purchase Exposition at St. Louis, 1904. This polish has been carefully prepared for the Automobile trade. It is also applicable to the carriage trade, or can be used on any varnished furniture or woodwork of any kind. It will remove stains, cover scratches; leaves the automobile with its original new lustre, without being sticky or greasy. Furnished in eight-ounce bottles. Guaranteed not to harm the finest varnish. For sale by all Automobile Dealers. Price 60 cents per bottle.

The Miller Automobile Jack

The Miller Automobile Jack is a quick acting, automatic lowering jack, designed especially for automobile use, and is adapted to the factory or garage as well as to be carried as a part of the equipment on motor cars. It is high-grade and one of the finest finished jacks on the market. We guarantee this jack for twelve months. The list price of the Miller Jack, $3.50 each.

Reliability

WHAT DOES IT MEAN?

It means that which merits confidence.

¶ There are two things which may be considered the limits of the motor car's future. One is economy and the other is proof that it can be depended upon.

¶ The motor car's abilitv to cover practically indefinitely 100 miles a day for every day, is sufficient evidence of its reliability, which would be more than any reasonable requirements it would be asked to meet in ordinary use.

¶ A regular Premier stock car started out on June 1st to cover at least 100 miles a day for 100 days—MORE THAN ONE-THIRD OF THE DISTANCE HAS BEEN COVERED WITHOUT EVEN ADJUSTING THE CARBURETER.

¶ Premier performance is such as to merit the utmost confidence in the ability of the car and the further fact of its selection as the Official Pathfinder for laying out the 1908 Glidden Tour—a task probably more difficult of accomplishment than any heretofore required of a fully equipped stock touring car—is only an additional evidence of the trustworthiness inspired by this car.

Send for catalogs and Glidden Tour booklet.

The Severest Tests

have demonstrated time and time again that the principles employed in

Timken Roller Bearings

are the only correct ones that insure perfect transmission of all power to traction use, eliminating both friction load and end thrust.

A Stoddard Dayton Stock Car equipped complete with **Timken Roller Bearings** finished April 12th, a ten-day century run, 1,000 miles over the roughest roads with all adjustments sealed, something impossible for a car equipped with the ordinary type of bearings to perform. This car, as do all cars of the **Stoddard Dayton** make, carries a full equipment of **Timken Roller Bearings,** as tests made under the most adverse and severe conditions have proven them an economical factor in the saving in wear and tear from strain alone.

And these are some of the reasons why more than **65 per cent.** of all the makers of high grade American Automobiles and over **90 per cent.** of the Commercial Truck builders are now using them.

Are you? If not, won't you let us give you some figures that prove. These are yours for the asking.

The automobile outlook for 1909

Every year since the inception of the automobile, public demand has drifted in certain directions and toward certain types of cars at certain prices. The tide has swelled from one extreme to the other; from the high priced car on the one hand to the "cheap" car on the other. There will continue still to be a limited demand for both. But the greatest popular demand will be for a good four cylinder car of ample size and power at about the price of the new

Cadillac "Thirty"

the four cylinder 30 H. P. large car of CADILLAC quality at $1,400.00, in which we have something which cannot possibly have any successful competition because no other factory is organized and equipped to build a car of its quality at such a price.

The dealer who handles the product of the old established, permanent and reputable manufacturer, whose name on the car is an absolute guarantee of its quality, and whose car shows itself to be so far superior in every way to every other car in the popular demand class, will be the dealer who will get the business.

There is reason to believe that the sale of automobiles during the coming year will be far greater than ever before and the dealer who is not prepared to meet the public demand with the car the public wants at the price the public is willing to pay, is sure to see a heavy balance on the undesirable side of his profit and loss account.

In addition to the "Thirty," we shall continue the world-renowned small cars, which have a place of their own to fill in the automobile world, together with other models which have made the name CADILLAC famous the world over for that which is proven to be best in automobile construction.

We have already closed contracts and accepted orders with deposits for a large portion of our 1909 product. There still remains some territory open and there is also other territory now in the hands of old dealers in which we desire to make changes. If you are a "live" dealer and want the line of cars on which you can make the most money, as well as the line which will afford the greatest satisfaction to your customers and yourself, write us.

1909 will be a CADILLAC year

THE MOTOR WORLD

Volume XVIII. New York, U. S. A., Thursday, July 9, 1908. No. 15

POPE RECEIVERS GET FREE REIN

May Continue Manufacturing for 1909—Would Sell Columbia Steel Stock—Apperson Rumor Denied.

In spite of the so-called banking or "note brokers" interests opposing any line of action other than a closing up of the Pope Mfg. Co. affairs to a point where they would get their money as quickly as possible, the receivers on July 7 obtained from Vice-Chancellor Howell, of the New Jersey chancery court, a general order permitting them to go ahead and carry on the business at the Hartford and Westfield plants for the season of 1909, and to buy the necessary material for and to manufacture 700 automobiles and 50,000 bicycles of the 1909 pattern.

This action is regarded as being agreeable to the wishes of the majority of merchandise creditors, who want to see the business regain its feet and are willing to allow a reasonable time to that end.

The demand for an immediate settlement of claims has been placated to a large extent by the issuance of an order looking to the payment of a second dividend of 25 per cent. on all allowed claims. The order directs the receivers to apply to the Superior Court of Connecticut for the transfer to the jurisdiction of the New Jersey court of sufficient funds to pay such a dividend to the creditors. The hearing on this application will take place in Hartford on July 21.

A proposition to sell $300,0000 worth, par value, of shares in the Columbia Steel Company, which were among the assets, to Howard Cole for $135,927.75 and a cancellation of the Pope indebtedness to the Columbia Co. amounting to $54,072.25, making in effect a total of $190,000, is being entertained by the receivers. The offer is subject to the approval of the court of chancery and the receivers have petitioned the court for direction as to its acceptance or rejection, the hearing to be held in Newark on July 14. The receivers declare it the most favorable offer made them for the property and incline to accept it. The hearing will permit whatever objections may be offered.

The attorneys for Louise Unzicker, who with others of her family, is the owner of the Western Wheel Works property in Chicago on which the Pope Co. has a 17 year lease at $25,000 a year, have been endeavoring to get an order compelling the receivers to pay into the court money to cover 25 per cent. of her claim each time a 25 per cent. dividend is paid the creditors. The money has been ordered set aside, but decision is reserved as to paying it into court.

Rumors that Apperson Bros. were negotiating for the Pope-Toledo plant, at Toledo, arose from the fact that R. D. Apperson, of Virginia, asked permission to examine it with a view to purchase. Receivers Scott and Yule granted this permission, but no definite offers have been made, and the Apperson in question has no connection with the Kokomo firm.

Stepney Sues on Spare Wheels.

"Spare wheels" are the subject of a suit brought in Portland, Maine, against the Burrowes Screen Co. by the Stepney Spare Wheel companies, who allege that the defendant is infringing their patent on the Stepney spare motor wheel. The plaintiffs claim basic patent rights on this form of accessory both in Great Britain, their native heath, and in the United States, where an American company with English capital is operating under license.

Closing Auto Vehicle Affairs.

The last rites over the bankrupt Detroit Auto Vehicle Co., of Detroit, Mich., have been set by the referee in bankruptcy as taking place on July 21, at which time the estate will be officially closed provided nothing untoward arises. All the creditors have been invited to attend a meeting in Detroit on that date, when the trustee's report and final account will be passed upon and the remaining funds divided.

ABSORBS AUTOMOBILE OFFSPRING

American Locomotive Drops Berliet—Parent Concern to Make "Americanized" Cars, Trucks and Cabs.

Changes involving the death of the American Locomotive Automobile Co. as a separate and subsidiary company of the American Locomotive Co., and the dropping of the name "Berliet" in connection with the product, have been announced by Vice-President Ball of the parent concern. The three-year contract with M. Berliet, of Lyons, France, under which the French Berliet was duplicated in the American Locomotive Co.'s factory at Providence, R. I., terminated on July 1, and has not been renewed, as a more distinctly American modification in the type of touring car is contemplated for the future together with a new line of trucks and cabs.

In announcing the changes, Vice-President Ball says: "The American Locomotive Company, having acquired all of the stock of the American Locomotive Automobile Company, has for corporation reasons absorbed that subsidiary company with several others which have heretofore led separate existences. The policy therefore is not one affecting the automobile company solely. The automobile business will be continued in the works at Providence, in the garage in New York, and in the agencies in various parts of the country on a larger scale than before. Besides continuing to make touring cars, the company has in prospect a business of considerable proportions in the production of trucks and cabs.

"The American Locomotive Co. made its original contract with M. Berliet for the purpose of purchasing experience. It has now acquired all that is to be learned of foreign design and construction, its organization is perfected and its productive plant skilled in turning out the finest work. While there will be no radical changes in the gen-

Digitized by Google

eral design of the cars with the dropping of the name Berliet, it will now be possible to make certain modifications of the French design which are desirable for American uses. It never was intended that any trucks or cabs should be built under the Berliet license. These, with the touring car, will now have the benefit of the eclectic combination of foreign and domestic practices that are now in vogue at the Providence factory.

"The personnel of the automobile department remains unchanged, Mr. James Joyce continuing as manager of the department, with R. B. Van Dyke in charge of the New York offices, Charles E. Davis as superintendent of the factory at Providence, and B. D. Gray as chief engineer."

Smith Speedometer Shows Assets.

The affairs of the R. H. Smith Mfg. Co., of Springfield, Mass., which on June 25 assigned for the benefit of its creditors, following the death of R. Hale Smith, its president, have cleared sufficiently under the work of the trustees to develop an inventory of its assets and liabilities. The total liabilities amount approximately to $60,000, while the assets are estimated to have an inventory total of $70,391.02

The items constituting the assets are set forth by the trustees as follows: 2,300 motormeter instruments in various stages of completion and parts for 700 additional instruments, $19,954.07; rubber stamp supplies. $15,960.61; machinery, tools and fixtures, $14,476.34; accounts receivable, estimated value, $17,500; Springfield Realty Trust stock, 833 shares at par value, $2,500. Of these assets, $11,500, at inventory valuation, were pledged as collateral security for bank loans, prior to January 1, 1908. None of the merchandise creditors was protected by security. The trustees, Robert A. Knight and Charles H. Beckwith, have discontinued the New York and Chicago branches for the sale of speed indicators, and the instruments now on hand will be disposed of in the regular course of business unless this department can be disposed of advantageously as an entirety. Before taking up the manufacture of speed indicators the company had long been engaged in making rubber stamps, and this branch, according to the trustees can be continued at a profit. The trustees therefore recommend that they be permitted to carry on the rubber stamp department as a means of conserving the best interests of the creditors.

Alexander Takes a Partner.

Associated with W. D. Alexander in his new jobbing enterprise in Atlanta, Ga., is George M. Seewald, for five years manager of the Atlanta branch of Morgan & Wright, covering five southern states. The new concern will be known as the Alexander-Seewald Company. Among other lines it has obtained the southern agency for Morgan & Wright tires.

The Week's Incorporations.

Dallas, Tex,—Dallas Motor Car and Transit Co., under Texas laws, with $6,000 capital. Corporators—J. A. Bergfield J. C. Hooper, J. E. Power.

St. Louis, Mo.—Eureka Motor Buggy Mfg. Co., under Missouri laws, with $50,000 capital. Corporators—John Woodburn, B. A. Wicks, Charles Zimmerman.

San Diego, Cal.—Tibbals Auto Supply Co., under California laws, with $10,000 capital. Corporators—W. L. Tibbals, San Diego, Cal.; L. H. McGowan, A. J. Scherer, Los Angeles, Cal.

Garwood, N. J.—Hicks Motor and Mfg. Co., under New Jersey laws, with $25,000 capital; manufacturing dynamos, motors, etc. Corporators—A. B. Grafy, H. E. Hicks, W. B. Elliott.

New York City, N. Y.—Fisk Rubber Co. of New York, under New York laws, with $5,000 capital. Corporators—William G. Philippean, Max Meyer, 2 Rector street, New York City, N. Y.; Alfred N. Mayo, Springfield, Mass.

New York City, N. Y.—Murray Hill Garage Co., under New York laws with $25,000 capital; manufacturing, dealing in and renting cars, carriages, wagons, boats, etc. Corporators—W. A. Mayon, S. C. Conger, J. S.Keith, New York City.

Wheeling, W. Va.—Triumph Automobile Tire Co., The, under West Virginia laws, with $1,000,000 capital. Corporators—Henry E. Keys, Charles O'Deer, W. E. Johnson, Homestead, Pa.; C. K. O'Hara, Akron, O.; K. P. Stewart, Wheeling, W. Va.

In the Retail World.

W. H. Tibbals, of San Diego, Cal., with L. H. McGowan and A. J. Scherer, of Los Angeles, has incorporated the Tibbals Auto Supply Co., to open a new supply house in San Diego.

William A. Blair has retired from the firm of H. A. Rowan, Jr., Co., owners of the Aldine Garage, 2028 Sansom street, Philadelphia. H. A. Rowan, Jr., the other member of the firm will continue the business.

The Ellis Motor Car Co., Newark, N. J., will move September 1st to a new building, 124-126 Washington street. Its present location at 222 Halsey street has been outgrown. The company handles the Pierce Arrow and Knox cars. W. H. Ellis is proprietor of the concern.

C. B. Peironnet and W. J. Dannatt, constituting the Clinton Automobile and Supply Co., of Clinton, Iowa, have taken over the business, garage and equipment of the Lamb Automobile Co. of that city. Val Bonney, manager of the business under the old name, will devote several months to rest and recreation.

Franklin After Southern Trade.

As "southern traveling representative" of the H. H. Franklin Mfg. Co., L. E. Hoffman has found the job all that the name implies, having just completed a 17,000 mile automobile business trip through the southern states after returning from a long trip in Central America and Mexico. Altogether he has been gone six months, placing agencies in southern cities and in Mexico City, Monterey, Torreone, Guadalajara, Aguas Calientes, Vera Cruz, Madeira, Yucatan, and Havana. Business conditions in the majority of the cities visited indicate a healthy and growing market for cars in districts where they have heretofore been regarded as impossible luxuries.

Morgan & Wright Make Unusual Sizes.

Tires of larger sizes through the small diameter than are ordinarily obtainable for certain size wheels are announced as among the new and unusual productions of Morgan & Wright, of Detroit, Mich. Of these a 31x4-inch Universal Dunlop tire is conspicuous since it is designed to fit perfectly a 30x3½-inch, 1908 Midgley rim. Similarly the new 33x4-inch Dunlop will fit a 32x3½-inch Midgley rim. These special sizes are recommended for use on rear wheels. The 40x4 inch regular clincher tire which is announced, has the distinction, according to its makers, of being the largest size pneumatic tire made in this country.

Ford Factory Plans Finished.

Final details of the immense new factory of the Ford Motor Co., on the old Highland Park race track property at Detroit, have been announced. The main building, which will be of reinforced concrete, steel and glass, will be 865 feet long, 75 feet wide, four stories high, and will have six acres of floor space, and in addition there will be a separate office building, a power plant and a group of saw-tooth roof outer buildings. Adequate light will be a feature of the main building, the glass in the windows totaling 52,453 square feet. The architect is Alfred Kahn, who designed the Pierce, Packard, Garford and Thomas plants.

Continental Promotes Competition.

Tire changing contests, to demonstrate the speed and facility with which its demountable rims and ready-flated tires may be handled, are being held at the various agencies of the Continental Caoutchouc Co. The first of these contests took place in Hartford, Conn., recently, at which the winner, Harold Green, did the trick in 58 seconds. This was followed by a contest in New York, at the Continental headquarters on Broadway, where the first prize was won by R. Piccoli, in 59 seconds. The third contest takes place in Boston in the near future.

Downing Goes to Studebaker.

W. S. Downing has resigned his position as sales manager of the Pope Motor Car Co., at Indianapolis, Ind., to become the Pacific Coast manager for the Studebaker Automobile Co., of South Bend, Ind. He will have his headquarters at San Francisco.

MAY MAKES AN EXPORT DECLINE

Number of Cars Shipped Abroad Less than a Year Ago—Parts Exportations Increase—The Summary.

An increase of something over $22,100 in the valuation of automobile components exported from the United States during the month of May last, served to curtail in part the loss due to decreased shipments of cars. This decrease was from 281 in May, 1907, to 229 in the corresponding month of this year. In values, the combined total of cars and parts were, respectively, $665,450 and $459,057, last year and this.

Gains in six of the divisions recognized by the Department of Commerce and Labor at Washington, also had a steadying effect. The principal source of this movement was France, which gained approximately $1,500, while South America, "Other Europe" and Germany, also contributed in amounts ranging through four figures. As for the countries revealing depreciating markets, the United Kingdom led, with no less than $103,088 decline. British North America, Italy, and Mexico, follow in this order, with $56,000, $31,000, and $30,000, respectively and in round numbers.

For the eleven months ending with May, 2,206 cars were exported, as against 2,567 cars during the corresponding period of 1907. The valuation of parts for this period shows the usual reversal, the increase being from $548,871 in 1907 to $588,401. The totals, including the parts valuations, however, reveal a loss of $203,062. The field is evenly divided in the matter of gains and losses for the period in question. Of the improving markets, that of the United Kingdom is the most noteworthy, with a gain of $283,834, France with $143,258, and West Indies and Bermuda with $42,360, following. Mexico proves to be the greatest loser, with a $383,500 drop, while British North Americt, and "Other Europe follow in this order. The record in detail follows:

	May		Eleven Months Ending May		
	1907	1908	1906	1907	1908
Automobiles and parts of:—					
*Automobiles	$618,018	$389,487	$2,957,748	$4,221,316	$4,008,724
Parts of	47,432	69,570		548,871	558,401

Imports Falling Off Rapidly.

During the month of May the total imports of foreign cars by the United States fell away nearly to the amount of $200,000. The exact figures for the month in 1907 and 1908, respectively, were 105 cars, value $333,657; and 72 cars, value $170,185. Component parts were imported to the value of $75,768 in 1907, and $42,515 this year. France and Italy were the countries most seriously affected. France, in May 1907, exported to the United States 76 cars, value $242,020. This year but 52 cars, value $122,952 were sent here; a decrease of nearly 50 per cent. Italy, in May, 1907, sent 16 cars, valued at $48,427, and in May, 1908, 15 cars, valued at $34,939. For the 11 months ending with May, the total figures are respectively, 1,113 cars, value $3,839,045, and 974 cars, value $2,346,613.

Hartford Rubber Running Nights.

Chafing under a delay of two days, made necessary by the taking of inventory last week, the Hartford Rubber Works Co. has taken steps to quickly regain lost working time, as night shifts were resumed on Monday and will be continued indefinitely, or until the catching up on orders is in sight.

Particularly gratifying to the company is the reception accorded the Hartford clincher tire, the sales of which have doubled and half doubled again this year.

Selden Parts with Palmer & Singer.

The Selden Motor Vehicle Co., of Rochester, N. Y., has discontinued its New York agency with the Palmer & Singer Manufacturing Co., and for the present the agency wil rest with E. T. Birdsall, the company's engineer. The latter has headquarters at 41 West Sixty-third street.

Overland Enlarging for Next Year.

The Overland Automobile Co., of Indianapolis, Ind., is at work on a large addition to its factory in preparation for the 1909 season. Manager John Willys is buying materials for a greatly increased production.

TIRES NOT MOTOR CAR PARTS

Entitled to a Lower Import Duty Even When Shipped with Machines—Importers Win in Court.

The long fought question as to whether tires imported with new machines are dutiable as rubber goods at 30 per cent., or as parts of an automobile and therefore subject to the 45 per cent. duty as being made principally of metal, upon being taken to the United States circuit court for the Southern district of New York, has been decided in favor of the automobile importers and adversely to the government.

The Auto Import Co., Archer & Co., and Massenat Deroche were the complainants against the action of the collector of customs at the port of New York in assessing duty on the tires that came with their imported motor cars at the rate which obtains for automobiles themselves, instead of at the lower duty. On the first appeal from the decision of the collector, the importers lost and the Board of United States General Appraisers upheld the collector's action, but the case was carried up with a different result, although the government has now in turn given notice of appeal to the circuit court of appeals.

The brief of the decision explains that "Automobiles were imported with tires accompanying them; but the tires had not, prior to importation been attached in such a way as to be capable of immediate use, and they were interchangeable and might or might not be used on the machines with which they were imported. The court held that the tires and the machines did not together constitute an entirety, but were dutiable as though imported independently.

"In order that merchandise that is distinctly a manufacture of one material, as a rubber automobile tire, shall be classified as a manufacture of another material, as an automobile in chief value of metal, it is necessary that the entire article manufactured should have existed as an assembled entity, so that it would be an invasion for the foreign maker to break the entity into fragments and expect each fragment to be treated as if complete in itself. But where an article has never been assembled abroad, it ought not for tariff purposes to be treated as if it had been so assembled."

District Judge Platt, in giving the decision, said in part: "In the cases at bar there is no evidence that the rubber tires in issue had been attached to the wheels of the automobiles in the country of production in such a way as to be capable of immediate use. It is to be observed that the tires are not so markedly a part of the automobile as the nuts, bolts, beams, angle iron, etc., because these latter things are individual to the particular make of machine and are intended to stay until worn out."

WHITE WINS

A Partial Summary of Victories, May, 1907-May, 1908

Perfect Score in Harrisburg Endurance Run

Tieing with three other cars in the contest of May 5th-6th, 1907. For the result of the "run-off," see below.

Fastest Time in Wilkes-Barre Hill-Climb

Defeating 45 high-powered gasolene cars, in the great contest on Decoration Day, 1907.

Fastest Time in Cleveland Hill-Climb

Defeating 40 high-powered gasoline cars.

Fastest Time in California Hill-Climb

Defeating the fastest of its gasoline competitors by nearly two minutes on the 2⅞ mile hill at Witter.

Perfect Scores in Sealed Bonnet Contest

Both White cars entered made perfect scores in this contest conducted by the Automobile Club of America.

Officially Observed Non-stop Run of 1871 Miles

Held under the auspices of the Royal Automobile Club of England and certified by that organization.

Fastest Time of the Season on the Track

One mile in 1:02, ten miles in 12:54, and twenty-five miles in 29:07 at the Santa Rosa Track Meet.

Officially Declared Most Efficient Car

In the South Harting hill-climb, conducted by the Royal Automobile Club, the White won the contest because it developed at the rear wheels a greater percentage of its assigned horsepower than did any other car. The rating assigned to the White was 50 horsepower.

Wins English Dust Trials

Proving officially that it raises less dust than any other car.

Clean Sweep in the Glidden Tour

Three White entries make three perfect scores.

Won Hower Trophy

The single White runabout entered in the Glidden Tour defeated a dozen high-priced gasoline runabouts competing for this prize.

Won California Reliability Contest

In the original contest held September 20th, two Whites tied with two gasoline cars. In the "run-off" held November 15th and 16th, both Whites made perfect scores, while both gasoline cars were penalized.

Won Quaker City Endurance Run

In this contest, held January 1st, 2d and 5th, the White vanquished 27 gasoline cars of 23 leading makes, winning the MacDonald & Campbell trophy.

Fastest Time in San Francisco Hill-Climb

Winning the free-for-all, the $2,500 class and the $3,500 class.

Fastest Time in the New York Carnival Hill-Climb

Making the ascent of Fort George hill in 32⅕ seconds, compared with the best gasoline time of 36 seconds; largest entry list of any hill-climb ever held.

New San Francisco-Los Angeles Record

The White car made the 478-mile mountainous journey in 17 hours and 17 minutes, cutting 56 minutes from the previous figures.

Double Victory in Harrisburg Endurance Run

The single White entry was the only touring car to make a perfect score, winning the principal 1908 trophy, the Board of Trade Cup, and also the 1907 prize in a "run-off" with last year's other perfect-score drivers.

Perfect Score in Endurance Runs at Boston, Detroit, Baltimore, Kansas City, Indianapolis and Atlanta

Strength of the Good Roads Movement.

What evidence was lacking to the popular mind hitherto of the strength which the good roads movement has attained is now afforded by the magnitude of the convention which was held in Buffalo, N. Y., this week. The cause of good roads has progressed practically without cessation since it obtained its first impetus at the hands of the bicycle industry some years ago. With the growth of the automobile movement the demand for improved highway conditions, which had been permitted to lapse to a certain extent, has been renewed with tremendous vigor. The contention which sometimes is made, that automobiles tend to injure the highways is a circumstantial and somewhat fortunate incident to the case, for, partly in self defense and largely because of the advantages to be obtained by the motorists, the automobile interests have been largely responsible for the present good roads agitation from which great benefits to all users of the highways are to result.

That two thousand or more delegates from all parts of the country are taking an active part in the present assemblage, that they are composed, not alone of the motorists but also of representatives of the American Road Makers' Association and the National Grange, is of tremendous advertising value to the cause. What the convention accomplishes in a definite and technical way may be considered from the present standpoint as hardly more important than this feature. The public arousal which may be brought by focussing general attention upon any subject is certain to carry in its wake results of the practical sort, such as the engineers and other experts at the Buffalo meeting are paving the way to accomplish. What this meeting may do for the United States and for America, the International Congress, to be held in Paris next October, on an even more ambitious scale, will do for the world at large.

The good roads movement is one of the biggest and most pregnant movements of which it is possible to conceive. Its problems change rapidly with the years and require a constant change of method to cope with them. In order to face these new conditions properly representatives of not one or two, but all interests which touch the highway in any sense, must be allied and to that alliance must be added that popular support which is merited by and accorded only to questions of truly world-wide import.

The Readjustment of Automobile Values.

Considerable stir is being created over the announcements by a number of the better known makers, of new models of the medium-powered, medium-priced order, and the various rumors that others are about to follow their lead. From this it is urged that the days of the high-priced car market are numbered and that the era of the low-priced car—that fetich of the man who cannot afford a car at any price, as well as of the man of moderate means and tastes—is about to arrive. As a matter of fact, neither of these assumptions is strictly true, though it may be a fact that the demand for machines of the super-elegant order, is being tempered somewhat by the limited return which they bring on their purchase price, and though it is unquestionable that in terms of mileage value per dollar, the cost of cars is being reduced.

As a matter of fact the man who is waiting for the day of the low priced car is likely to wait for some time to come, and probably is doomed to partial disappointment in the end. It is possible to build cars to sell at very low prices. When their cost of operation is considered, however, they are not as cheap as might appear from a casual perusal of the maker's catalogue. The few exceptions to the rule, are the product of wholesale manufacture and are likely to remain exceptions for some time to come.

The true inwardness of the movement for cars of moderate power and price is that the public has begun to demand a car of sterling qualities first and always, and has learned to discriminate in making its choice. Furthermore, it is fast coming to demand a car which will satisfy a moderate demand for speed and carrying capacity and develop high qualities of endurance and reliability. Finding that such a car can be made and sold under proper conditions for what has come to be recognized as a moderate price, the call for this type of machine is rapidly increasing. The fact that in price as in other respects, it suits the tastes of a much larger group of buyers than the more pretentious machine, accounts for the growth of the demand, and reinforces the logic of the makers who are supporting it.

It has been demonstrated beyond all manner of doubt that in the construction of two cars of, say, 40 and 30 horsepower, respectively, it is impossible to save more than 10 per cent. over the cost of the larger in building the smaller—provided only that quality of material is retained, and the design kept practically uniform. The same number of parts are present in the two, the same processes of manufacture must be carried out. Practically the only structural difference is in the amounts of metal entering into them, and this difference is relatively small. Hence the relation between the costs of different powered models made by the same manufacturer and uniform in construction, is readily explained, and in many instances responds very closely to this law—if such it may be termed.

That the "poor man's car" ever will become a reality in the bargain counter sense, is never more unlikely than to-day. That cheap cars are available at present and at various prices, and that they will continue to be so, is beyond question. The production of the strictly high grade car at what are now regarded as low prices, however,

Digitized by Google

is highly problematical at present, except in rare cases where huge outputs and close figuring triumph. The fact of the matter is that a readjustment of values is in progress, and that in that readjustment, a certain standard type of high grade product at a reasonable price, all things considered, is being evolved. Subsequently, it is likely that the development of the lower priced car at a proportionate cost will be given greater prominence. But this must be done according to a rational system, and more or less in accordance with the "law" above cited.

What England's New Patent Law Means.

Although it has been permitted to pass with but cursory notice in this country, the new provision of the British Patents and Designs Act of 1907, which is to go into effect on the 28th of next month, is destined to have a broad and searching effect on the imports of the United Kingdom—an effect which must be felt in no small measure in this country as in others, and one which will spare no industry nor combination of industries. Its stipulation that any British patent may be declared void if the article which is protects is manufactured "exclusively or mainly" abroad, means, in a word, that exporters of patented articles who have relied upon the British market hitherto, must either dispose of their manufacturing rights to local producers, or themselves establish local factories.

Just how this will affect the automobile industry in the United States, is open to conjecture. Of the total of nearly $460,000 worth of exports for the month of May last, $132,663, or 29 per cent. went into Great Britain, while the totals for the 11 months ending with May, show that very nearly one-third of our foreign business during that period was done in England. Furthermore, it is well known that many of the better established makers here, have strengthened their position by taking out foreign patents on certain exclusive features of their product, and that although these grants by no means cover the entire machine, they are of considerable value in protecting certain characteristic features.

In the fullest interpretation of the act, then, it will mean that the manufacturer whose car is equipped with, say, an original carburetter which it is desired to continue to protect in England, must either lease the manufacturing right abroad, or contrive to have his agents assemble all but the most salient features from imported parts, which means practically, British manufacture under American license. To the maker who has a sufficiently large amount of business there already, the obvious course of establishing local assembling factories is open. The small maker, and the maker doing a limited English business, however, are likely to suffer.

In the accessory field, the effect is likely to be less marked, though the burden will be none the less felt by a few makers and jobbers who handle a considerable amount of trade in that quarter. In that case it means a practical elimination of exportation to England, or else the abandonment of patent protection.

The bulk of the burden will fall upon Germany, it appears. According to a statement attributed to Sir Alfred Jones, no less than 25,000,000 pounds sterling of foreign, principally German, capital have been invested in England already as a result of the law. Several German manufacturing and exporting firms have been forced to augment their own resources very extensively, while owing to the loss of exports, the German business has fallen off correspondingly. The German Union of Industrialists even went to the length of attempting to secure an extension of one year on the time limit set for the law to go into effect, but without success. As the manufacturing costs average much higher in England than in Germany, the conduct of the new British subsidiary factories must be more expensive than manufacturing under the old conditions has been, so that counting the cost of the new establishments, the income from German capital is likely to be greatly curtailed in the near future so far as this one field is concerned. Consequently the situation is regarded as being exceedingly grave.

Eclipse of the "One-Man" Idea.

Individual brilliancy, while perhaps being rewarded more liberally in a financial way than ever before, is no longer being "played up" so heavily as in the past, as the basis for the reputation of automobile manufacturing concerns. The "one-man" idea is being eclipsed by that mysterious thing known as "organization," and the manufacturing companies, instead of being mere hastily formed groups of men and capital to exploit and advance the respective mechanical and business conceptions of bolder pioneers, have become more institutional in character, with conservative tendencies and certain well defined lines of policy.

COMING EVENTS

July 9, Buffalo, N. Y.—Start of American Automobile Association's annual reliability touring contest for the Glidden and Hower trophies.

July 14, Spokane, Wash.—Spokane Automobile Club's hill climbing contest.

July 15, St. Paul, Minn.—Automobile Club of St. Paul's meet at Hamline track.

July 15, Huntington, N. Y.—Huntington Automobile Club's carnival and races.

Sept. 1, 2, 3, and 4, Chicago, Ill.—Chicago Motor Club's postponed 1,000-mile reliability run.

November 26, Savannah, Ga.—Automobile Club of America's (New York), 400 miles outlaw race for foreign cars.

December 31-January 7, New York City—American Motor Car Manufacturers' Association's annual show in Grand Central Palace.

January 16-23, New York City—Association of Licensed Automobile Manufacturers' annual show in Madison Square Garden.

In many respects this is of decided benefit both to the public and the trade, sparing them the sudden and ill-considered surprises which are almost invariably incident to complete "one-man" power. The conservatism which makes more deliberate the movements and actions of large organizations is by no means the same thing as the "dry rot" which occasionally afflicts large corporations to the advantage of their more active individual rivals, but is a healthful governor on progressive ideas and enthusiasms. When an established concern of reputation announces either a new car or a new selling policy, it is not likely to be the result of a noon-hour inspiration or impulse of the day before, but the product of the combined thought and experience of many able minds. If it relates to business policy it has been decided upon only after much conference with the interests it would be likely to affect and after consideration from every possible side, while in the case of a mechanical production, it is only offered to agents and the public after long tests and an absolute ascertainment of its value.

That every concern must needs avail itself of the best talent which it can gather to its aid is of course a truth forced upon it by competition. But for its most perfect efficiency there must ever be the strong spirit of organization and settled policy rather than dependence upon individual performance.

FIFTY-FIVE CARS IN GLIDDEN TOUR

Composition of Teams that Start from Buffalo To-day—List of Contestants for the Hower Trophy.

Fifty-five cars set out from Buffalo to-day for a 1,700 mile journey through seven States, which will consume fifteen days. The accompanying map shows the route. Thirty of the cars are contestants for the Glidden trophy, in ten teams of three cars each, while 14 runabouts are in rivalry for the Hower trophy. Eleven official and non-competing cars accompany the contestants. The tour is the fifth annual touring contest for the Glidden trophy and the second annual for the Hower trophy. Although the tour idea originated in 1905 when Charles J. Glidden put up a perpetual trophy, this is the first year that the affair has been frankly labeled a "contest," and trade rivalry is on this occasion very keen.

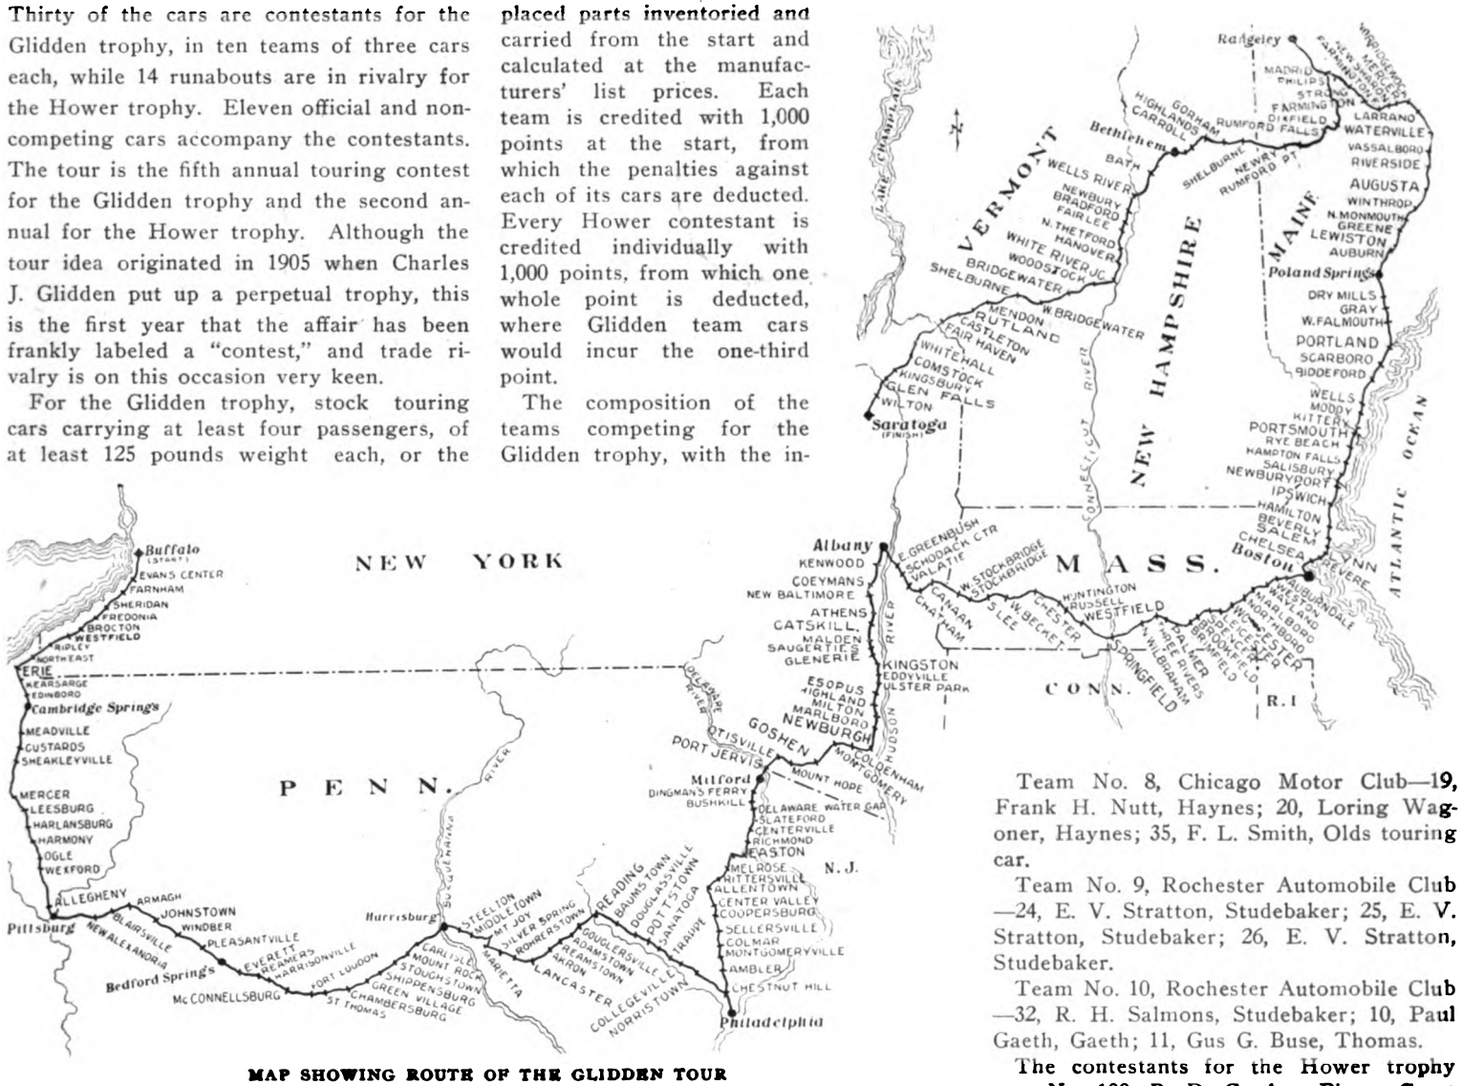
For the Glidden trophy, stock touring cars carrying at least four passengers, of at least 125 pounds weight each, or the equivalent in ballast, enter in teams of not less than three cars each, under the name of a club affiliated with the A. A. A. Any club may have more than one team. All replacements, repairs and adjustments must be made during the running time of the car. All replacements must be made with parts inventoried and carried at the start of the tour, except tires. Tire repairs alone are not charged against the running time of a car. Only the operator and the one mechanician may work on repairs. Each competitor furnishes an observer who serves on a different rival each day. The trophy goes to the club having the team with the most points left after all penalty deductions. For the Hower trophy, runabouts are the contestants. The trophy goes to the individual car having the most points left after all penalty deductions.

Since every Glidden team happens to be composed of three cars, the penalties will be one-third of a point per minute or fraction thereof that a car is either ahead or behind time at controls, in excess of the two minutes leeway allowed for variation in timepieces, and one-third of a point per dollar or fraction thereof of value of replaced parts inventoried and carried from the start and calculated at the manufacturers' list prices. Each team is credited with 1,000 points at the start, from which the penalties against each of its cars are deducted. Every Hower contestant is credited individually with 1,000 points, from which one whole point is deducted, where Glidden team cars would incur the one-third point.

The composition of the teams competing for the Glidden trophy, with the individual contestants' numbers, which are given preceding each contestant's name, respectively, is as follows:

Team No. 1, Automobile Club of Buffalo—1, Charles Clifton, Pierce Great Arrow; 2, Charles Clifton, Great Arrow; 3, J. W. Maguire, Great Arrow.

Team No. 2, Columbus Automobile Club—5, E. H. Parkhurst, Peerless; 6, E. H. Parkhurst, Peerless; 7, E. H. Parkhurst, Peerless.



Team No. 3, Automobile Club of Syracuse—12, H. H. Franklin, Franklin; 13, John Wilkinson, Franklin; 14, G. H. Stillwell, Franklin.

Team No. 4, Bay State Automobile Club—21, Frank E. Wing, Marmon; 22, W. C. Marmon, Marmon; 23, W. C. Marmon, Marmon.

Team No. 5, Chicago Motor Club—15, Andrew Cuneo, Rainier; 27, J. B. Eccleston, Oakland; 28, E. M. Murphy, Oakland.

Team No. 6, Cleveland Automobile Club—29, A. R. Davis, Garford; 30, A. R. Davis, Garford; 31, A. R. Davis, Garford.

Team No. 7, Automobile Club of Buffalo—4, R. M. Owen, Reo; 8, R. M. Owen, Premier; 9, H. O. Smith, Premier.

MAP SHOWING ROUTE OF THE GLIDDEN TOUR

Team No. 8, Chicago Motor Club—19, Frank H. Nutt, Haynes; 20, Loring Wagoner, Haynes; 35, F. L. Smith, Olds touring car.

Team No. 9, Rochester Automobile Club—24, E. V. Stratton, Studebaker; 25, E. V. Stratton, Studebaker; 26, E. V. Stratton, Studebaker.

Team No. 10, Rochester Automobile Club—32, R. H. Salmons, Studebaker; 10, Paul Gaeth, Gaeth; 11, Gus G. Buse, Thomas.

The contestants for the Hower trophy are: No. 100, R. D. Garden, Pierce Great Arrow; No. 101, R. M. Owen, Reo; No. 102, W. H. Vandervoort, Moline; No. 103, Charles Clifton, Great Arrow; No. 104, George A. Weideley, Premier; No. 105, John Breyfogle, Gearless; No. 106, F. A. Barton, Franklin; No. 107, G. P. Moore, Stoddard-Dayton; No. 108, E. W. Shirley, Overland; No. 109, H. C. Tillotson, Stoddard-Dayton; No. 110, J. N. Willys, Overland; No. 111, J. N. Willys, Overland; No. 112, R. G. Cox, Stoddard-Dayton; No. 113, A. L. Kull, Gyroscope.

Official cars—95, R. M. Owen, Reo, official; 97, R. M. Owen, Reo, pilot; 98, R. M. Owen, Reo, pilot; 99, Charles Clifton, Great Arrow, chairman's car; 96, Packard, red cross car.

ONE-TWO-THREE FOR GERMANY

Teutons Capture the Honors in the Grand Prix—Double Tragedy in Last Round of the Contest.

For the first time since 1903, Germany triumphed in the conquest of a great international road race, when Lautenschlager, driving a Mercedes, won the Grand Prix, after covering 478.3 miles of the course in 6 hours 55 minutes and 43⅘ seconds, or at an average rate of 69 miles an hour. As if this spectacular victory of one man and one car were not sufficient in itself, the triumph was reinforced by the winning of second and third place by Hemery, he of Vanderbilt Cup, and later of Ormond fame, and Henriot, both driving Benz cars, while of the seven leading cars at the finish, five were German.

America's sole representative, Strang, in the Thomas car, was hopelessly beaten from the start. It was said at the time, that an accident prior to the race had disabled the transmission in such a way as to eliminate the reverse and two of the forward gears. In the face of this handicap, he had the courage to start, and succeeded in completing the first round in 53 minutes 44 seconds. More difficulties developed later, however, and he was forced to withdraw.

The race, which was held last Tuesday, 7th inst., over the Dieppe circuit, and covered practically the same ground as last year, was by all odds the most spectacular which has been seen since the inauguration of the Grand Prix. For the first time, the engine dimensions were limited, the cylinder bores being restricted to 155 millimeters, or 6 inches and a trifle over, so that a certain uniformity of power output was required. The stroke required in the winning Mercedes was 6.6 inches, and the rated output, like that of the majority of the cars, was 120 horsepower.

Several accidents, involving two fatalities, marred the running of the contest. On the last round of the race, the Panhard, driven by Cissac, was overturned at a sharp corner, owing to the ripping off of one of the tires. Both Cissac and Schaub, his mechanic, were pinned beneath the machine, and were killed almost immediately. Harrison, driver of the British, Weigel, car, also was badly injured by the overturning of his machine, but it is thought he will recover.

Forty-nine cars started in the race, of which number only 23 survived. From the very beginning a furious pace was set up, and excitement was at a fever heat among the spectators. Szisz (Renault), Thery (Brasier), and Bablot (Brasier), all broke the record for the round on their first lap. Wagner (Fiat), and Salzer (Mercedes), however, bettered even that, and the former captured the record for the fastest round, averaging the entire distance at the rate of 78½ miles an hour, and thus adding one more laurel to German's wreath.

A breeze sprang up as the second lap was in progress, and rapidly ripened into a gale, which somewhat impeded the drivers. The leaders soon began to weary of their pace and one by one fell back, while the usual tire troubles also began to have their effect. Lautenschlager forged to the front in the fourth lap, and held that position to the end of the race, driving with remarkable uniformity, and in luck as to tires and minor mishaps.

France's consolation was that the drivers of the two Benz cars which finished second and third, were Frenchmen, and that Hemery distinguished himself by the most signal display of pluck ever witnessed in connection with an event of this description. When the race was half over a stone thrown up by the wheels, struck his goggles, shattering them, and driving a bit of glass into one of his eyes. He continued on the the tribune and called for a physician, but upon examination it was found that the particle could not be removed. Refusing to discontinue the race, he submitted to an injection of cocaine, and continued to the dramatic finish.

Italy, represented by six cars at the start, had the discomfort of seeing all but two of them drop out of sight, only Cagno and Fournier, the latter veteran winner of the Gordon Bennet race of 1901, finishing in 11th and 20th places, respectively, with their Itala cars. Two of the three Belgium and two of the six English cars survived.

The crowd was the greatest ever assembled for such an occasion, and assumed stupendous proportions, even on the first day, when the "Little Grand Prix" was run. Reports of the magnitude of such throngs always are uncertain, but the estimate of "nearly a million," in this connection, is one not easily forgotten. The drivers who finished the course, with their total times, were as follows;

No.	Driver, Car, and Country.	Time.
1	Lautenschlager, Mercedes, Ger.	6:55:43⅘
2	Hemery, Benz, Germany	7:04:24
3	Henriot, Benz, Germany	7:05:13
4	Rigal, Clement-Bayard, France.	7:30:36
5	Poegge, Mercedes, Germany	7:32:31
6	Joerns, Opel, Germany	7:39:40
7	Erbe, Benz, Germany	7:43:21
8	Dimitrievitch, Renault, France.	7:54:12
9	Heath, Panhard, France	7:55:36
10	Perpere, Germain, Belgium	7:59:08
11	Cagno, Itala, Italy	8:07:56
12	Gabriel, Clement-Bayard, Fr.	8:11:44
13	Courtade, Motobloc, France.	8:12:42
14	Garcet. Motobloc, France	8:19:56
15	Caillois, Renault, France	8:19:57
16	Janatzy, Mors, France	8:24:44
17	Jarrott, Mors, France	8:39:20
18	Brabazan, Austin, England	8:42:50
19	Resta, Austin, England	8:46:50
20	Fournier, Itala, Italy	8:47:20
21	Opel, Opel, Germany	9:08:11
22	Degras, Germain, Belgium	9:13:34
23	Farman, Panhard, France	9:24:40

The winner's average speed was less than that of Nazzaro, last year's winner.

Germany's last notable victory was in 1903, when Jenatzy, also driving a Mercedes captured the Gordon Bennet Cup, which had been held by England. The two succeeding Bennet cup races were won for France by Thery, while the first Grand Prix, in 1906, was captured by Sisz, also for France. Last year, Nazzaro's victory upraised Italy's standard for the first time.

As a sort of curtain-raiser to the main race, and on the day previous, the Grand Prix de Voiturettes was run. Actually it was a huge demonstration of the type of light, low-powered car, which is having such tremendous vogue in Europe at the present time. Guyot, driving an 18 horsepower, two-cylinder Delange, captured the honors in this event, driving a steady race at the remarkable speed of 80 kilometers or nearly 50 miles an hour. The Sizaire & Naudin and Lion cars, which finished second and third, were driven by Naudin and Goux.

The limiting conditions for entries specified that the cars should weight 600 kilograms, or about 1,300 pounds, and that they should be listed at from $1,200 to $1,500. There were 47 starters, and 32 survivors. The race was spirited, though by no means spectacular. Accidents were of a minor nature, none of them resulting seriously to the contestants, despite the fact that no less than five of the pigmies were overturned at one point or another in the course. Like the big race on the following day, this was a Michelin tire event, no less than the first five cars carrying this equipment, while the first three places in the Grand Prix itself, were secured on the same reliable basis.

Exposition of Road Making Planned.

An extensive exposition of road-making materials and accessories is being organized as an adjunct to the International Congress which is to be held in Paris, October 11 to 18. How inclusive the scheme is, is shown by the fact that among its exhibits will be numbered such literature as maps and plans of construction, and data on cost of upkeep; tar, stone and wood paving materials; road rollers, tar-spraying apparatus, tools and appliances. One section will be devoted exclusively to a display of wheels for heavy vehicles, spring and elastic wheels, tires, anti-skidding devices, and springs and exles.

Not Running in Presidential Race.

Somebody has been going over the pages of the new Boston directory to cull out distinguished names borne by residents of that city. Among the names found was that of William H. Taft, who is proprietor of a garage in the Brighton district.

Salt Lake Organizes a Club.

The Salt Lake Automobile Club has been organized in Salt Lake City, Utah, with the following officers: O. H. Hewlett, president; L. L. Terry, vice-president; J. E. Jennings, secretary; C. R. Pearsall, treasurer.

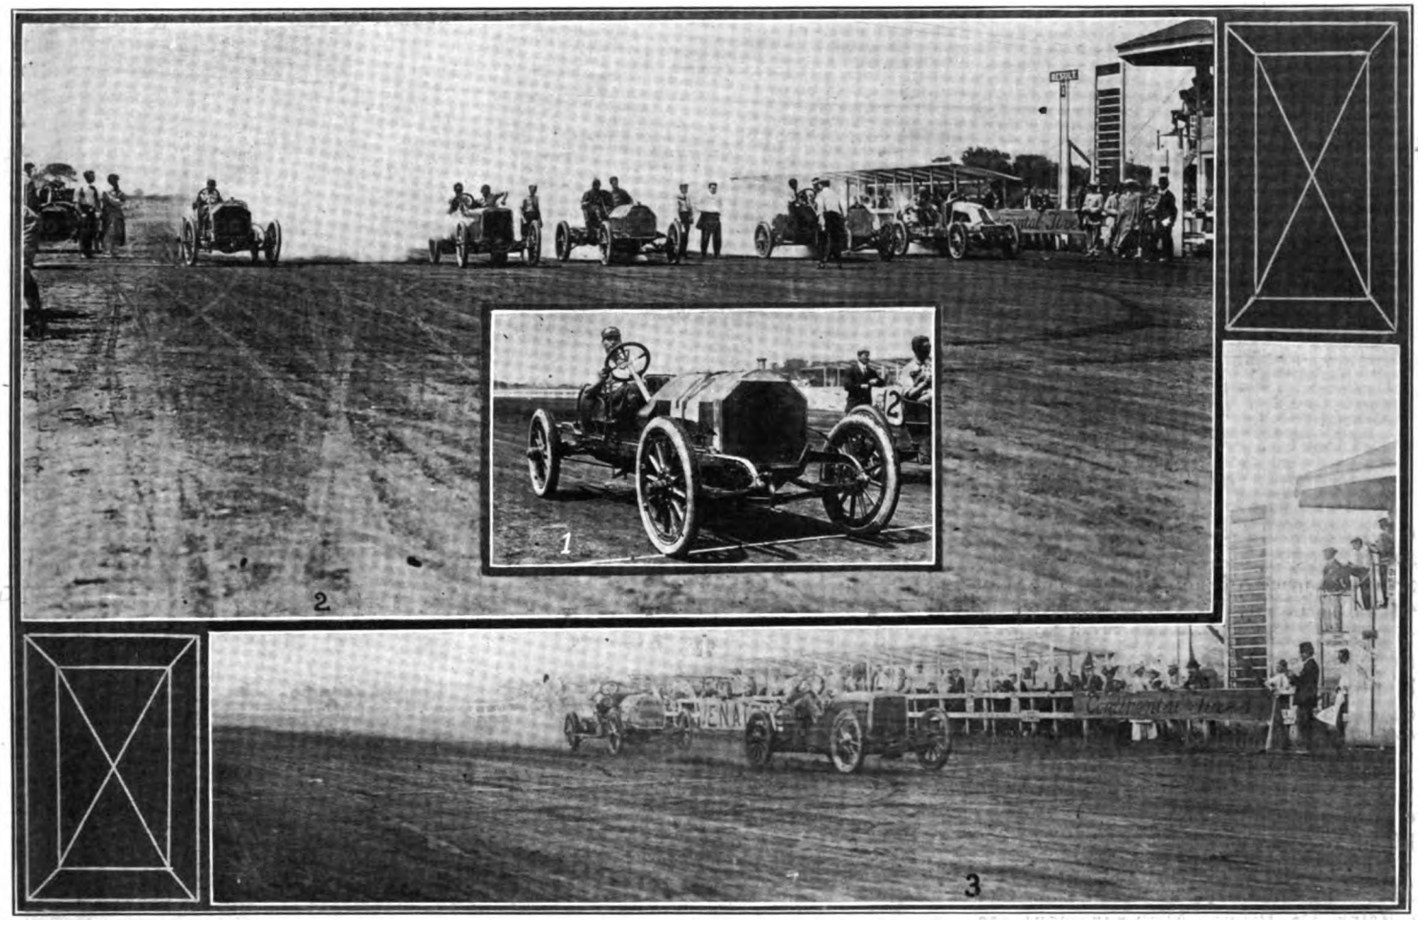
RAINY DAY MEET AT LONG BRANCH

De Palma Captures Two Events at Elkwood Park Opening—Two Thrilling Accidents Mar Exciting Contests.

Intermittent showers and a sloppy track resulting in several accidents, marred what otherwise would have proved a successful meet at the Elkwood Park mile track, near Long Branch, N. J., on Saturday last, 4th inst. It was the first meet of the newly organized Elkwood Park Automobile Association, and had the weather been favorable the attendance doubtless would have been record-breaking, several thousand spectators being in the stands despite the threatening weather.

A heavy shower at noon made the holding of the races seem doubtful but as it cleared up afterwards the promoters decided to take a chance and some time after 2 o'clock the first event—five miles for stripped stock cars—was called. Al Poole, on an Isotta, stalled his motor at the start and threw a shoe in the first lap, two things which put him out of the running before the race was well under way. Ralph De Palma, Allen-Kingston, jumped into the lead at the start, with Stewart Elliott, American, second, and Arthur Warren, Stearns, in third position. This order was maintained until the tape, De Palma, who drove a clever race, winning handily.

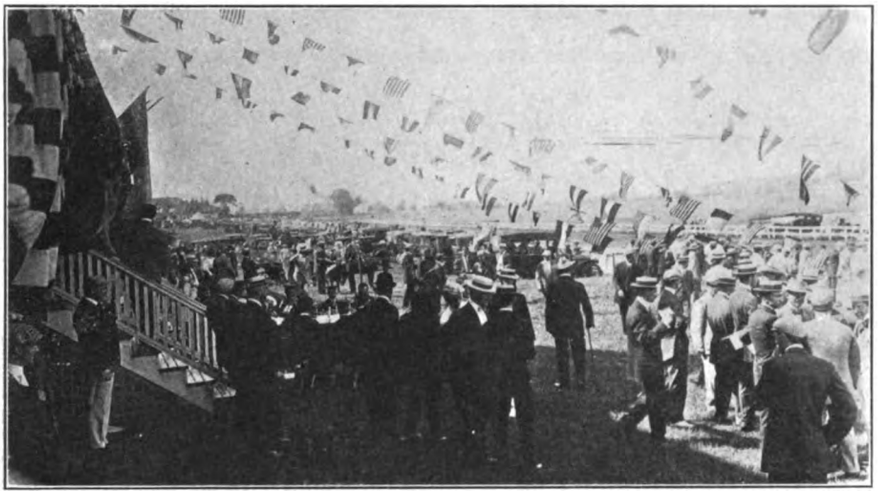


The amateurs had their innings in a ten miles open, which brought out five starters. James Doig, Stearns, proved the quickest starter, but he had not covered one lap before Stewart Elliott, in the American, got the lead. Elliott lapped W. B. Anderson, Welch, in the eighth mile and continued until the finish, with Doig second, and T. J. Scully, Packard, third. Time, 10:53.

Another shower came up about the time the amateur event was disposed of and after waiting a long time for it to blow over the 50 miles free-for-all, which had a cup and a cash prize of $100 to the winning driver, was started, with seven cars in line. The first smashup came in the first lap when Warren in the Stearns, and Fisher in the Auto car rounded the upper turn into the stretch together. The Stearns skidded in an oily pool, slewed diagonally across the track and turned turtle as it crashed into the fence. Warren jumped, but Crawford, his mechanic, was pinned beneath the car, and while in that position the Autocar banged into it. The driver and mechanic of the latter escaped injury, but the car was put out of commission.

Crawford and Warren were badly hurt. The former's left foot practically was severed from the body, while Warren had his collar bone and one leg broken. Both men were removed to the LongBranch hospital and a short time afterward the same ambulance had to make another trip. The second accident occurred in the 29th mile. Bellows, in the Renault, while in a brush with De Palma on one of the curves, hugged the pole too closely and went through the inner rail, tearing away thirty feet of the rotten fence before it overturned. Bellows was hurled some distance through the air while Meyer, his mechanic, in attempting to jump, landed head first, but broke his fall with his arm, which broke. Both men were badly bruised and shaken up. The accidents were too much for some of the spectators and they left the grounds.

Ralph De Palma assumed the lead after the fifth mile, and from then until the finish he was never headed, finishing the distance in 55 minutes 59⅗ seconds, fast time when the muddy track is taken into consideraton. Henry Lozier, in a car of that name, had covered 47 miles, and C. Frewin, Welch, 44 miles, when De Palma crossed the tape.



One of the best events of the meet was the 100 miles race for cars of the Briar-

1. RALPH DE PALMA (ALLEN-KINGSTON) WINNER IN TWO EVENTS. 2. LINED UP FOR START OF FIVE MILES RACE.
3. STEWART ELLIOTT (AMERICAN) WINNING EVENT FOR AMATEUR DRIVERS.

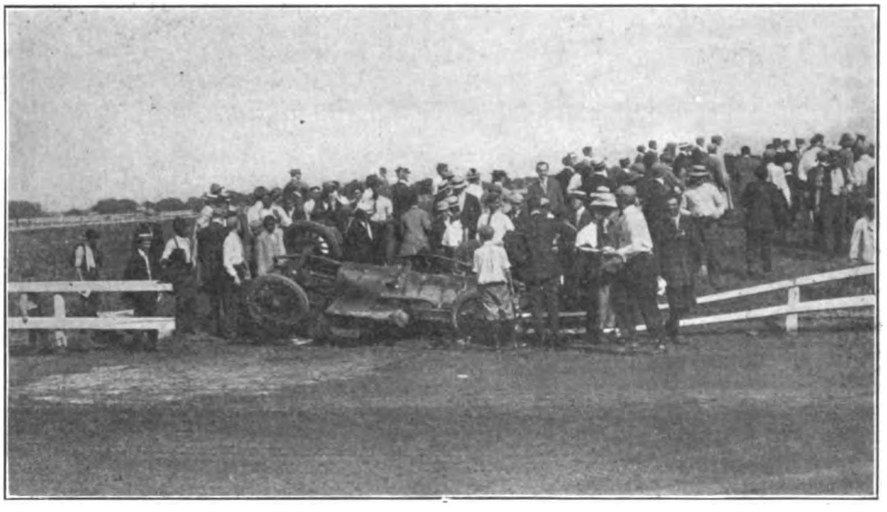
Digitized by Google

cliff race type, but it was due more to luck than to anything else that no casualties occurred. Slow time resulted as the drivers did not take any more chances than were absolutely necessary after the two accidents in the previous race, but despite their cautiousness the cars skidded all over the track at times. Heavy showers came down intermittently during the progress and the last half of the race was over a course so thick with oil and water that only in places was the surface of the track visible. The fight between Poole and De Palma was well worth the price of admission. The pair kept up a running fight from start to finish, and they were never separated by more than a half lap. The outcome was doubtful until Poole finally crossed the line 12 seconds in advance of young De Palma. Harry Lozier finished six miles behind, and Prossen in the Bianchi was fourth, having covered 90 miles. Both the Isotta and the Allen-Kingston cars were fitted with Michelin tires, which gave them three firsts out of a possible four. The summaries:

SCENE ON THE LAWN IN FRONT OF THE GRAND STAND

Five miles for stripped stock cars—Won by Ralph De Palma, Allen-Kingston; second, Stewart Elliott, American; third, Arthur Warren, Stearns. Times, 5:25⅘, 5:31⅗, 5:38⅗.

Ten miles, for amateur drivers—Won by Stewart Elliott, American; second, James Doig, Stearns; third, Thomas J. Scully, Packard. Times, 10:53, 11:07⅗, 11:42⅗.



Fifty miles, free-for-all—Won by Ralph De Palma, Allen-Kingston; second, Harry Lozier, Lozier; third, Charles Frewin, Welch. Time, 55:59⅗.

One hundred miles for Briarcliff type cars—Won by Al Poole, Isotta; second, Ralph De Palma, Allen-Kingston; third, Harry Lozier, Lozier. Time, 2:10⅗.

Two New York-Paris "Racers" Crippled.

Ill fortune has beset both the American and the German contestants in the New York-Paris "race" since the last bulletin of their progress appeared in the Motor World. Both the Thomas car and the German Protos car have suffered serious delay, and this proved especially trying to the American crew because of the fear that the Germans again had got ahead of them. The fear, however, proved groundless. The Protos car did not reach Omsk until the 3d inst., and it was in such need of repairs that it had to remain there until the arrival of new parts required.

Shuster, on the Thomas, left Omsk early in the morning on Wednesday, 1st inst., and got along smoothly until after crossing the Irtish river, 30 miles from Omsk, a swamp a mile wide was encountered. When nearly across the car cut through the straw with which the road had been covered to prevent wagons sinking, and the strain attending the attempt to get out cracked two teeth of the driving gear, leaving the car unable to run.

WHERE ARTHUR WARREN'S STEARNS TURNED TURTLE

It was necessary to get a block and tackle and haul the car out of its position. Men, women, and children from the nearby village of Marianovka meanwhile gathered to see the car, and, learning its plight, all of them volunteered to help. They all took hold of the 200-foot rope, and in an intended triumphant march, dragged it into the town.

Shuster immediately returned to Omsk in a peasant car to get the extra driving gear, which had been expected at Omsk. The car was able to proceed on the 4th inst., though still severely crippled.

Bermuda Losing Through Exclusion.

As a result of Bermuda's exclusion of the automobile, commercial interests already have begun to suffer, owing to the large number of absentees during the season. It is stated by the former transient inhabitants of the island that many of the more charming scenes are inaccessible without the fast conveyances, and that they cannot reach all the drives or visit all the beautiful sections in Bermuda in horse drawn vehicles on account of the distances. As a result most visitors are denied many of Bermuda's beauties. Already a road or speedway for the exclusive use of automobiles and fast horses, running from St. George's to Ireland Island, has been proposed, the idea being to support it by the collection of tolls.

Hoffman First in Race at Tuxedo.

W. M. V. Hoffman, driving a Packard, won the automobile race that formed a feature of the Fourth of July games at fashionable Tuxedo Park, N. Y. The course was 1½ miles long and Hoffman covered the distance in 1:07. Richmond Talbot, Fiat, was second, and W. M. Weygant, Locomobile, third.

California Reliability Run Postponed.

The reliability run promoted by the Automobile Dealers' Association of California, which was to have been held July 3 and 4, has been called off. Conflicting dates made the entry list small and for this reason an indefinite postponement was deemed advisable.

KEEN COMPETITION AT WILDWOOD

Schill Lowers Local Mile Record—Fourteen Perfect Scores in Reliability Run Preceding the Carnival.

A crowd estimated at 20,000 witnessed the Independence Day meet of the Motor Club of Wildwood, N. J., held on the level Central boulevard, the feature of which was the breaking of the record for that mile straightaway stretch by Paul Schill, of Philadelphia. Schill drove a 120 horsepower racing car and covered the distance in 42⅗ seconds, which was 1⅗ seconds better than the time made by Montague Roberts at the meet last year.

Schill's fast flight was accomplished in the time trials for all classes and in this event the contestants had better opportunity to speed than in the stock car events that preceded the piece de resistance of the day. The stock cars had to go against a strong head wind, but when the time trials were put on the direction was reversed. William Haupt, the Philadelphia young man who has been doing hill climbing stunts all the season, disappointed his many followers as they confidently expected him to win in a walk, and they had backed up this expectation with real Quaker City spending paper. Haupt made three trials, but he failed to touch Schill's record, his fastest trial being recorded in 43⅗ seconds.

Rain in the early morning cast a gloom over the thousands of people that poured into the resort, but before 10 o'clock the sun came out strong and from then until the close of the meet the weather man was favorable. Despite the immense crowd that lined both sides of the boulevard, the policing by the North Philadelphia Boys' Brigade was all that could be desired.

Although the nine events were not filled as well as they might have been the competition was keen throughout, and in spite of the head wind the stock cars made fast time. Walter Cram, driving a Mitchell, won in the class for cars between $1,251 and $2,000, in 1:33, but this time was reduced in the class for cars between $2,001 and $3,000, when Frank Lescault, Palmer & Singer, defeated Len Zengle, Pennsylvania, and George Davis, Apperson, in this order in 1:13⅕.

Thomas cars got first and second in the event for cars between $3,001 and $4,000, W. Mullen finishing first and W. M. Magraw second. W. J. Sprankle, in a Premier, was third. Mullen also won a special event.

Schill won both the open for four cylinder gasolene cars and the free-for-all, but his fastest time was made in the time trials. The summaries:

Gasolene cars selling under $1,250—Won by Edward Wilkie, Buick; second, Walter Cram, Mitchell; third, W. H. Ford, Overland. Time, 1:28⅕.

Gasolene cars selling between $1,251 and $2,000—Won by Walter Cram, Mitchell; second, W. H. Ford, Overland. Time, 1:33.

Gasolene cars selling between $2,0001 and $3,000—Won by Frank Lescault, Palmer & Singer; second, Len Zengle, Pennsylvania; third, George E. Davis, Apperson. Time, 1:13⅕.

Gasolene cars selling between $3,001 and $4,000—Won by W. Mullen, Thomas; second, W. F. Magraw, Thomas; third, W. J. Sprankle, Premier. Time, 1:04⅖.

Open for four cylinder cars over $4,000—Won by Paul Schill, Fiat; second, Charles J. Swain, Apperson; third, H. Goodin, Stearns. Time, 0:53⅕.

Six cylinder cars—Won by F. J. Nordell, Chadwick; second, Joseph Parkin, Jr., Parkin. Time, 1:00.

Free-for-all—Won by Paul Schill, Fiat; second, Joseph Parkin, Jr., Parkin; third, W. Chalmers, Chalmers-Detroit. Time, 0:49⅘.

Time trials—Charles J. Swain, Apperson, 0:52⅖; Paul Schill, Fiat, 0:44⅗, 0:45⅖, 0;42⅖; William A. Wood, Cleveland, 1:13⅗; Joseph Parkin, Jr., Parkin, 0:53⅗, 0:53; W. Chalmers, Chalmers-Detroit, 0:51⅖; George E. Davis, Apperson, 1:06⅗; Edward Wilkie, Buick, 1:13⅗; Walter Cram, Mitchell, 1:18; W. F. Magraw, Thomas, 1:01⅕; William Haupt, Chadwick, 0:45⅘, 0:43⅘, 0:42⅗.

Special event for gasolene cars selling between $2,001 and $3,000—Won by W. Mullen, Thomas; second, Len Zengle, Pennsylvania; third, George E. Davis, Apperson. Time, 1:02.

The feature during the morning was a decorated parade on the boardwalk in which a score or more of cars participated. The prize for the best decorated cars went to W. Wayne Davis, Matheson.

The curtain raiser to the meet on Saturday was a reliability run from Gloucester City, N. J., a few miles below Philadelphia, to the shore, and although a number of cars started many had to turn back because they had failed to comply with the New Jersey laws. Twenty-four of the starters finished, however, with fourteen of that number in the perfect score class. As there was only one prize, a cup, it was agreed that the perfect scorers should draw by lot, the unlucky thirteen receiving certificates. The cup was drawn by J. M. Hendricks, Chadwick, the other finishers being:

W. F. Magraw, Thomas; H. Greenwood, Premier; D. H. Beck, Packard; E. Humphreyville, Stanley; B. Thorpe, Studebaker; W. H. Taylor, Reo; E. A. Wright, Oldsmobile, J. D. Avil, Pope-Hartford; W. J. Spronkle, Premier; J. H. Hendricks, Chadwick; Walter Cram, Mitchell; E. A. Jackson, Mitchell; W. Freitg, Mitchell; D. Little, Mitchell; A. J. Bankard, Dragon; A. A. Jones, Ford; W. T. Wilkinson, Packard; W. H. Ford, Overland; J. W. Parkin, Parkin, and Turner Sharp, Winton.

An open air show Friday evening arrested the attention of the boardwalk promenaders, the racing cars being on exhibition.

SURPRISES AT BALTIMORE MEET

Morton Beats Favorites in Pimlico Handicap—Leinbach Wins a Championship—Wagner Exposes Trickery.

Although there was a multiplicity of events on the boards at Baltimore on the Fourth, more than 3,000 persons turned out to witness the race meet projected by the Motorcar Racing Association. Louis Bergdoll, of Philadelphia, who had been advertised as one of the features of the meet, and the only man looked upon to have a chance against E. L. Leinbach, the local, failed to show up, but despite his nonappearance the events were run off smoothly and without accident, excepting in the motorcycle match race, when Thomas skidded in a wet spot and ran into the fence.

The ten miles Pimlico handicap proved the feature automobile event of the meet and it resulted in some surprises. Leinbach was on scratch, with Wallace Hood, Thomas, of Washington, on ten seconds. The wise "fans" had it all doped out that there was nothing to the race but Leinbach first and Hood second. They were, consequently, somewhat surprised when Hood, after making a spurt at the start, faded away in the ruck, while Leinbach could not make up the distance because of the fast pace set by Morton out in front. Roy Stains and Morton held together most of the way, until a mile to go, when the latter took the lead and sprinted for the tape. Leinbach got an easy third.

The Maryland runabout championship at 10 miles created some interest and Leinbach was the favorite. Starter Wagner discovered two tanks on Hood's car and would not let him start. This left Leinbach with practically no opposition and after nosing out a lead at the start he cakewalked home in blue ribbon fashion.

Three starters lined up for the baby runabout event at five laps, and Jefferson Davis assumed command of the run at the start. He was not allowed the position long before Robert F. Kaehler's little Ford rushed to the front and after that there was nothing to it but him.

As the 50 miles event was for cars of 45 horsepower and under, Leinbach did not have a chance for a walkover. Morton jumped into the lead at the start and ran in front from then until the finish. The second Pullman car dropped out on the 28th mile with tire trouble, and John Auchfield finished second.

While these cars were tuning up for the race a motorcycle match between Mangold of Washington, and Thomas of Baltimore, was arranged. Thomas got off first to a flying start, but on the backstretch Mangold overhauled and passed. At the three-quarters pole the watering cart had left a wet spot and Mangold slowed when he saw it.

Digitized by Google

Thomas took a long chance and tried to come through on the pole. His machine slipped from under him and he bumped into the fence. He was considerably bruised and cut, but was able to hobble off the track.

Mangold won the five miles piston displacement handicap for motorcycles, starting with 20 seconds handicap. Thomas started from the same mark and the fight between the pair was interesting. W. S. Fisher, a 30 seconds man, was third. The summaries:

Five miles for runabouts costing under $1,250—Won by Robert F. Kaehler, Ford; second, Jefferson Davis, Cameron; third, George E. Norwood, Overland. Time, 6:59.

Ten miles, Maryland runabout championship—Won by E. L. Leinbach, Stearns; second, Roy Stains, Pullman; third, Robert Morton, Pullman; fourth, J. F. Brown, Autocar; fifth, E. H. Freas, Autocar; sixth Chester Smith, Autocar. Time, 11.04⅗.

Five miles for stock touring cars between 20 and 40 horsepower—Won by Robert Morton, Pullman; second, E. L. Leinbach, Moon. Time, 6:06.

Five miles motorcycle piston displacement handicap—Won by M. E. Mangold, Indian (20); second, Chic Thomas, Indian (20); third, W. S. Fisher, Indian (30). Time, 5:49.

Ten miles free-for-all handicap—Won by Robert Morton, Pullman; second, Roy Stains, Pullman; third, E. L. Leinbach. Stearns. Time, 10:36.

Fifty miles for stripped stock cars not exceeding 45 horsepower—Won by Robert Morton, Pullman; second, John Archfield, Autocar; third, A. W. Behrens, Maryland; fourth, J. F. Brown, Autocar. Time, 57:08.

One mile motorcycle match—Won by M. E. Mangold, Indian. Time, 1:20. Chic Thomas fell.

Somerville's Fourth of July Parade.

Automobile owners contributed largely to the success of the ambitious celebration of Independence Day which was held in Somerville, Mass. Nearly 100 cars were included in an automobile parade over a twelve miles route. They moved in four divisions, the first consisting of decorated vehicles and the last comprising specimens of the vintages ofearly days in the history of motoring. Three prizes were offered for competition in the decorated division. John H. MacAlman won the first prize with his large touring car which was decorated with wistaria and yellow fabric. Mrs. F. A. Dutton, who won second prize, drove a large car covered with rambler roses and laurel, even the wheels being masses of floral beauty. Mrs. Fred C. Kendall, third prize winner, had a very pretty turnout, her runabout being trimmed with wistaria, while Mrs. Kendall and her companion, Mrs. G. L. Wehre, wore white gowns and purple picture hats, carrying parasols to match. The route of the parade was profusely decorated.

WESTCHESTER WANTS FAIR PLAY

Prominent Residents Organize a Roads Association—Aims to Secure Sane Enforcement of Automobile Laws.

With the lofty purpose of "arousing and solidifying public opinion against unnecessarily severe automobile laws and ordinances," among its objects, the Westchester Roads Association, composed of residents of Westchester county, N. Y., has been incorporated. That among its objects also is numbered the purpose of protecting the interests of Westchester county real estate, also is to be inferred from the list of officers composing its directorate, as well as from the direct avowal of Secretary John R. Faure, who explained, in reference to the organization of the association:

"Something must be done for the protection of real estate values in Westchester County. Many good people come riding through the county, fall into a foolish automobile trap, are held up, arrested, fined, and subjected to a great deal of unwarranted annoyance and sometimes humiliation. . . . . Of course, some automobilists ought to be arrested, but it is the ridiculous laws and ordinances and the ridiculous enforcement of them that is hurting the county."

That the association has not been formed without due provocation, is shown by the fact that nearly the whole of Greater New York is at present encircled with a belt of speed traps, most of which are worked with great vigor and small regard for the personal feelings of the motorists. A bright and shining light in contrast to the general rule in this respect, is the chief of police of Port Chester, N. Y., who instead of establishing speed traps, makes it a practice to deliver a printed card of welcome to visiting motorists, which bears a polite request that the speed laws be not violated in his particular domain.

The officers of the Westchester Association are: President, I. D. Bristol, Chappaqua; vice-president, J. Mayhew Wainwright, Rye; treasurer, Walter W. Law, Jr., Briarcliff Manor; secretary, John P. Faure, Ossining. The vice-presidents in addition to Mr. Wainwright are Seth Low, Bedford Station; V. Everit Macy, Scarsborough; John McKesson, Jr., Mt. Kisco; J. J. Riker, Port Chester; F. C. Stratton, Mt. Vernon, and F. M. Warburg, White Plains.

Putting the Traps out of Business.

The best offset to speed traps is observance of the law by automobilists. This fact was illustrated on Sunday, 5th inst., by the poor returns in fines imposed through the operation of a trap established by the authorities of Hempstead, L. I., on the Bethpage turnpike. A stretch of the pike was measured off and a number of deputies were posted there with stopwatches. Instead of the large number of fines that were expected from arrests there were only two drivers arrested and one was fined $25 for going at what the deputies said was 64 miles an hour, while the other man paid $10 for traveling at 34 miles an hour. One of the drivers arrested notified the Long Island Automobile Club of the location of the speed trap and the club sent out men with cards asking drivers to slow down through the district, the result being that the deputies found their occupation gone from then on, as none of the motorists drove their cars at a faster pace than is allowed by law.

At a meeting of the Massachusetts Automobile Owners' Association, held in Boston on Thursday, 2d inst., it was voted to expend a considerable sum of money to rid the Commonwealth of automobile traps. The plan is to have men in khaki uniform stationed at or near places where the police have located traps, and to ask every automobilist to drive slowly through the particular part of the highway which is being guarded. A card will be handed to every automobilist, and it is expected that this work of the association will have a beneficial effect. The card will read as follows: "Please respect the wishes of the people of this town and drive slowly. Automobile Owners' Association, 1016-1017 Beacon building, 6 Beacon street, Boston. Francis Hurtubis, Jr., Counsel. Telephone, Haymarket, 970."

Atlantic County Again Polices Roads.

At the instigation of the local farmers, the Atlantic County (N. J.) board of freeholders, last week adopted a resolution for the reappointment of seven special automobile constables to do duty on the county highways during the summer. A movement was on foot to eliminate this year, the special constabulary, which was appointed last year for the first time, it is said. The farmers, getting wind of the attempt, circulated a petition which, reinforced with more than 200 names, was presented to the board at its last meeting, when the desired action was promptly taken. The appropriation required for the policing of the roads in this way provides for a salary of $60 a month for each of the special officers.

Political Caravan a Big Success.

The unique trip taken by the Illinois delegates to the National Democratic convention, from Chicago to Denver in five Studebaker automobiles, has not only given the delegates themselves a good time and a novel experience, but has been a source of gratification to its promoters because of the entire success with which the project was carried out. No small part of the honors is claimed for the Diamond tires with which the cars were equipped, the only tire trouble in the whole distance and for all five machines being four punctures, every original tire making the entire trip and arriving in Denver in good condition.

EXPERTS DISCUSS ROAD PROBLEMS

Three National Bodies and Many States Represented at Buffalo Convention—Important Resolutions Adopted.

With the unanimous adoption of the set of resolutions reported by Charles Thaddeus Terry, chairman of the committee on resolutions and counsel for the American Automobile Association, by which the American Roadmakers' Association, the National Grange and the American Automobile Association pledge themselves to work for the election of national and State legislators who will support the uniform State motor vehicle bill proposed by the A. A. A. and the enactment of the Federal automobile registration bill, the Good Roads and Legislative convention, which was held in Buffalo on Tuesday and Wednesday of this week, showed the first tangible result of the conference which had already given promise of playing an all important part in the development of American highways.

The convention opened in Buffalo, N. Y., on Tuesday with an attendance well up to the expectations of the promoters. Three national organizations were represented—automobile men, farmers and road makers—making the convention the most important and influential for the improvement of the highways that has ever been held in this country. The business of the convention consisted in the main of addresses by men who are recognized authorities on the subjects on which they spoke. A practical as well as educational feature of the program was provided by showing the delegates different kinds of highways in the process of construction, for which purpose several miles of roadway in the vicinity of Buffalo were exhibited in various stages of completion.

One of the important papers read was that of State Engineer Frederick Skene, of New York, embodying a brief historical sketch of the road system of New York State. In regard to the importance of the highway improvement propaganda, he said:

"The necessity for the improvement of the highways of this State is now so well established that argument is scarcely necessary, but in case objections should be raised to the cost of the work, it is well to bear in mind the fact that during the period of 10 years prior to the inauguration of highway improvement by State aid, the United States Government statistics showed a decrease in farm values in only four States of the Union, the greatest occurring in the State of New York and amounting to upward of $70,000,000. Resting, as our prosperity does, upon the financial welfare of the farmers, there can be no question but that any moneys expended for the improvement of the means of intercourse and the transportation of the 12,000,000 tons of farm produce annually raised in this State will ultimately result in benefit to the whole State."

L. W. Page, director of the United States Office of Public Roads, touched upon the delicate subject of "The Effect of Automobiles on Public Roads." He said:

"The pneumatic tire or any type of tire which propels a vehicle," said Mr. Page, "must have sufficient tractive resistance to overcome the load of the vehicle. This, of necessity, must cause a shear on the road surface which varies with the weight and speed of the vehicle. The broken stone road surface has little power to resist a shearing stress, consequently the fine material of which it is composed is thrown into the air. Once lifted from the road, this fine material is subject to the effect of air currents generated by the car body, and subsequently by the wind. In this manner large quantities of the material of which the road is composed are carried from the road and must eventually be replaced, or the road will rapidly deteriorate. Aside from the dust carried from the road in this manner, this shearing force of the motor car has a decided disintegrating effect on the surface of the road."

Of the two remedial courses at hand, one was that of constructing new roads in such a manner as to reduce to a minimum the formation of dust, and the other, to treat existing roads with materials which will give the same results, he stated. How these will work out in practice he did not attempt to predict.

Other prominent speakers were: F. N. Godfrey, master of the New York State Grange; Senator Jotham P. Allds, of Norwich, chairman of the Joint Legislative Committee; Stephen Ryan, State road director in New York State; A. W. Campbell, deputy minister of public works of the Province of Ontario; James H. McDonald, president of the American Roadmakers' Association; Horatio S. Earle, State highway commissioner of Michigan; Joseph W. Hunter, State highway commissioner of Pennsylvania; A. N. Johnson, State engineer of Illinois; R. D. Beman, deputy State highway commissioner of Pennsylvania; James E. Owen, of the Newark (N. J.) Board of Trade; Robert B. Caverly, president of the Automobile Club of Washington, D. C.; William L. Raeder, president Board of Trade, Wilkes-Barre, Pa.; Charles J. Glidden, of Boston; Horatio S. Earle, State highway commissioner of Pennsylvania; Robert P. Hooper, chairman Good Roads committee, American Automobile Association; Harold Barker, chairman Massachusetts highway commission; J. W. Abbott, ex-United States highway commissioner for the Rocky Mountain and Pacific Coast States; ex-Governor N. J. Bachelder, of New Hampshire, master of the National Grange, and A. R. Pardington, general manager of the Long Island Motor Parkway. The discussion touched on all aspects of the highways problem as it exists to-day.

FOREIGNERS FROWN ON A. A. A.

International Committee Refuses Courtesy of a Hearing—A. C. A.'s Victory Threatens Complications.

What it hailed as a strategic and signal victory for the Automobile Club of America over the American Automobile Association in the fight which the former is making to wrest away the control of automobile racing in the United States, took place at the annual meeting of the committee of the international association of recognized automobile clubs on July 6, at Dieppe, France, when the committee decided to ratify the action of the sporting committee of the Automobile Club of France in threatening disqualification for any French constructor who would take part in this year's Vanderbilt cup race under A. A. A. auspices, unless the Ostend rules are adopted. The committee further decided to recognize only the Automobile Club of America in relation to international racing affairs so far as the United States is concerned.

Although W. K. Vanderbilt and A. G. Batchelder endeavored to appear before the committee to present the statement of the American Automobile Association, they were denied admittance, while Dave Hennen Morris, for the Automobile Club of America was given a hearing. The A. A. A. side of the controversy fell to Count Adalbert Sierstorpff, president of the German Automobile Club, and he set forth that the A. A. A. is the larger and more powerful organization, that its control of American racing is legitimate, and that it had never been properly notified of the adoption of the Ostend rules, which have not been observed in making the plans for the Vanderbilt event.

The committee, however, felt piqued at the A. A. A. disregard of its rules governing international racing events, and after much heated discussion decided that for the present it would recognize only the Automobile Club of America, with whom it has for some years been on terms of reciprocity.

This action may in no small degree be attributed to the very active campaign that the Automobile Club has been making in the foreign press and by personal influence to persuade the racing interests on the other side of its magnified position and importance in the sport, as opposed to the apparent indifference of the Association as to the international situation. That the affiliations of the A. A. A. with the Amateur Athletic Union and through it with the governing bodies of all sports across the water will embarass the association of recognized automobile clubs in its ill-advised action, however, is a certainty, and a subsequent recession from the position it has taken may be looked for.

LAW BARS IMITATION PRODUCTS

Decisions Stamping Their Sale as Unfair Competition in Trade—Lack of Patent or Trademark Non-Essential.

Closely allied to the patent infringement and price cutting evils which so strongly menace the stability of all trade interests, is the imitation of wares, which constitutes a direct encroachment on the proprietary rights of the original manufacturer, even though no absolute patent or trademark infringement may exist. In many instances where specific protection does not exist the copyist may be held in check by the application of the trade mark law, under the head of "unfair competition,"—a phrase which should carry a broad and clearly defined meaning to every manufacturer and dealer.

A most suggestive case in point is that of the well known manufacturer of ignition apparatus, who found that the reputation of his product was being assailed because of the failure of certain of his specialties to give service for the full length of time which they might with reason be expected to last. After a long and searching examination by the manufacturer's experts, it was discovered that the cause of the trouble was in the wearing parts, which had been replaced by others made in imitation of the original by an unscrupulous manufacturer. The manufacturer believed that such pernicious practices could be stopped, and to the end of stopping them, put the matter in the hands of his attorney for action by law. Instantly the cause of the trouble was removed, by the simple process of calling to the attention of the imitating manufacturer the several decisions covering this point, which the courts had rendered. The offending maker saw the light, and averted a law suit by ceasing the practice of supplying parts which so closely imitated the original.

This case was placed in the hands of T. F. Bourne, 220 Broadway, New York City, whose views concerning the bearing of patents on the price cutting situation, were printed in these columns recently. When seen by a Motor World man early this week Mr. Bourne proved willing to talk of the steps which may be taken in suppressing imitation, under the head of unfair competition. His definition of the phrase which, probably has no specific meaning to many to whom it should be familiar, is as follows:

"'Unfair competition' is a term broadly used to express the doctrine that one person may not so dress up his goods, or the packages containing the same, that dealers may be enabled to palm them off upon the public as and for goods of the original manufacturer, irrespective of any particular trade mark rights that such manufacturer may have. This is very important in many instances, as where a manufacturer has built up a valuable trade without depending upon a trade mark, and the public has become acquainted with his goods by reason of their particular appearance or by the style of package or appearance of the label thereon. If others were permitted to sell their goods having such near resemblance to those of the original manufacturer as to be likely to deceive, a great injury would be done to such manufacturer, as well as to the public.

"The courts are very strict in restraining unfair competition, and to obtain such protection it is not necessary that a manufacturer have a strict technical trade mark for his goods," he continued.

"In the case of Church et al. vs. Russ, 99 Fed Rep., 278, the court held:

"'The underlying principal of each case (unfair trade and technical trade mark) is the same, namely, the prevention of that which in its operation and results, and usually in intention, is a fraud upon the public, and an injury to the rival trader.'

"With respect to a trade mark, irrespective of unfair competition, in Gannett vs. Rupert, 127 Fed. Rep., 962, the court said:

"'It is of no moment that the proof fails to show deception, confusion or injury to any marked extent. Such proof is unnecessary where infringement of a valid trade mark is clearly established.'

"In Consolidated Ice Co. vs. Hygeia Distilled Water Co., 151 Fed. Rep., 10, regarding the infringing trade mark, the court said:

"'It is enough that it is so used as to be likely to produce confusion as to the origin of the article to which it is applied. This sufficed to warrant the granting of an injunction. . . . . '

"I have referred to the trade mark cases above to show the analogy to cases on unfair competition in trade. There are two recent cases showing how far the court has gone in restraining unfair trade, even though the plaintiff had no patent or trade mark.

"A manufacturer of tobacco had for a number of years placed tin tags of peculiar shape, with a dark background and a word thereon, upon tobacco plugs, and had largely advertised the tobacco. Later the defendant put upon the market a cheaper grade of tobacco with plugs of the same size and shape, with tags thereon of the same size, shape, style and colors, the only difference being in the name, which the defendant did not copy, and which name could be distinguished at a short distance. The evidence showed that the simulation was intended, and did in fact deceive customers who intended to buy the plaintiff's tobacco. It was held that the same constituted unfair competition and entitled the complainant to an injunction. In this case the question of technical trade mark was not the point in issue.

"In another case, Yale & Towne vs. Alden, 154 Fed. Rep. 37, a manufacturer of padlocks who made a lock upon which there was no particular patent or trade mark, brought an action to restrain the defendant from selling padlocks in imitation of the appearance of plaintiff's padlock. The court said:

"'A comparison of the exhibits satisfies us beyond any doubt that the defendant had so closely copied the plaintiff's padlock in form, size, coloring, lettering and details of finish that his articles are likely to induce purchasers to buy his padlocks supposing them to be the padlocks of the plaintiff. . . . . The defendant has, with a purpose taken the design and dress of the plaintiff's padlock. He has carefully copied it, differentiating his own from it in minor details probably intending to escape the charge of infringement; but he has gone a step too far when he has produced a padlock which to casual observation is substantially identical in appearance with the plaintiff's. His apparent purpose was to extend his trade with retail dealers and supplant the plaintiff's sales to such dealers by furnishing them with an article which could be sold readily to customers as the article made by the plaintiff."

"The defendant was restrained from thus imitating the style and dress of the plaintiff's goods.

"The foregoing extracts show the dangerous ground to traders who copy the goods of others, whereby to enable the substitution of the copy or simulation for the original product, and where such acts are liable to cause confusion and deception the courts will not hesitate to restrain the same."

Motor Vehicles Multiplying in Saxony.

Statistics covering the use of motor vehicles in Saxony show that their use is increasing at a rate which is nothing short of remarkable. Up to January, 1907, 805 automobiles were registered. At the beginning of this year, returns covering the registrations for last year revealed a total of 1,352. The total number of vehicles including motorcycles, increased from 2,221 to 3,259, comparing the registrations of last year and the year before. Of the total number registered at the beginning of this year, 1,580 were used for technical and business purposes, 302 were employed by physicians, surveyors, etc., and the astonishingly low proportion of 1,182 for purposes of recreation.

New Jersey Registration Large to Date.

Registration figures at the office of J. B. R. Smith, State commissioner of motor vehicles for New Jersey, show that the total registration under the new law to July 1st was 11,400 machines. The revenue received by the State from these registrations was $83,850, which sum, together with all other income derived from the same source, will be used for road maintaining. Up to July 1st of last year, 8,521 machines were registered, the amount received being $41,800. The total registration for the year 1907 was 17,694 machines, bringing in a revenue of $85,694.

MILLENNIAL JOYS FOR MOTORISTS

International Automobile League Proclaims Message of Bedrock Prices and Universal Convenience.

That sadly misused individual, the "private owner" or "consumer," for whom many pretentious sounding organizations have in the past been promoted, may take heart again despite the failures and "four-flushing" of previous efforts, because a new one has been started upon which he may set his hopes of deliverance from the ogre of "agents' and middlemen's profits." The new movement has its home in Buffalo, N. Y., and bears the impressive name of the International Automobile League (Incorporated, $50,000), which the promoters condense to "the I. A. L."

While just to start with the I. A. L. only pretends to reduce the cost of automobiling to its members by selling them certain brands of tires and accessories at less than the list prices, yet it has much greater things in store for them after it gets going well. Not the least of these is the opportunity which it is going to give them to invest in the stock of the "League's own rubber factory," the construction of which would permit the League to get "tires equal to those now costing $130 for $40; when it will be able to get tires equal to those costing $75 for $25; when the equal of tires now retailing for $45 will be bought for $15, and when an equal will be found for tires now retailing at $15 for $5, and still pay its stockholders handsome dividends."

All that the League needs is 50,000 members who will buy their tires from it. Thus provided with customers the organization could safely "have tire factories of its own for the manufacture of tires exclusively for its members."

But for the immediate present the I. A. L. contents itself with outlining the advantages of the magnificent conception on which it is at work for the benefit of those who join its membership. For the tourist there are grand things in prospect. The booklet which the League is issuing with a view to enlisting interest and eliciting ten dollar bills for memberships, tells about it thus:

"The automobile is becoming more popular every day as a means of touring. Long trips in automobiles are the order of the day now, but one drawback to the average owner is the expense and this is by no means confined entirely to hotel and garage accommodations. The running of the automobile eats up a lot of money itself. It is here again that the plan of the International Automobile League has especial merit. The League proposes to have in every city, town and hamlet in the country, tire houses, supply houses, garages, hotels and gasolene stations where the presentation of the League's membership or identification card or official automobile tag will have the same value as if presented at the houses representing the League in your own city. The line of tire houses, supply houses and garages will, therefore, stretch from coast to coast, so that your I. A. L. tag will be as good in 'Frisco as in New York, as good in New Orleans as in Duluth; as good in Toronto or Montreal, as in Hamilton or Windsor."

As to the potency of the I. A. L. tag, the promoters modestly refrain from intimating that the condition of its being "as good in 'Frisco as in New York," etc., is not a mere futurity but is probably an actuality at the present time.

"Quick additions to the ranks of the I. A. L.," the booklet continues, "will aid much in its further development and in the force of its organization, bringing additional benefits to its members, in that the League will be in a better position to make arrangements for special prices with houses at present outside its influence."

To lend conviction to the printed matter sent out, various pictures are introduced, suggesting the function of the I. A. L. in actual life. On the third page of the booklet is a picture of a doorway from which is emerging an automobile. At the side of the door is a large card, put up in time so that the photographer could get it in conspicuously, proclaiming that special garage service rates are given members of the I. A. L. No other garage sign or indication that the place photographed is really a garage appears in the picture, and no identification is possible from the caption, "One of the I. A. L. garages where special rates are given to members of the league." On the fifth page appears a half-tone of two automobiles on a country road, which is explained by an imaginary colloquy underneath, in which Tourist asks Farmer: "Can you tell me the name of the I. A. L. hotel in the city, please?" To this Farmer, in order to prove to the reader the completeness of the I. A. L. service, replies like a flash: "You will find the names on the I. A. L. signs just down the road." The names of the city or the road are not supplied with the picture.

Similarly in the next illustration, Tourist stops Pedestrian to find out where there is an I. A. L. garage, but Pedestrian dodges by telling tourist to keep on until he finds an I. A. L. sign. Unfortunately the tourist may still be driving vainly over the broad land trying to find either an I. A. L. hotel or garage, as no pictures are shown disclosing him arriving at either the one or the other, or even finding an I. A. L. road sign.

Lest any doubts arise as to there being I. A. L. hotels or supply stations, however, two especially taken photographs are reproduced, one showing the brass nameplate of an hostelry, with a paper "I. A. L." placard pinned below it, and the other in front of an automobile supply store, with an "I. A. L." card tacked below the window, where it will show up well in the picture. The top of the latter illustration is cut off at a point which conceals to some extent the store sign, so that it is impossible to even guess where it is located or the name of the proprietors. The location of the hotel is also in doubt. Nevertheless it appears from the booklet that all I. A. L. members can get special rates by going to these two places.

Most staggering of all is a picture "showing strings of tanks containing gasolene for use of members of the I. A. L." If any doubts existed as to the immensity of the organization, this illustration is calculated to banish them. For as far as the eye can reach there stretches a railway track on both sides of which are enormous Standard Oil tanks. Possession of the contents by the I. A. L. is suggested, but not positively asserted, by a temporary paper sign tacked to a cross bench, which latter was set in the middle of the railroad track when the I A. L. photographer snapped his camera.

An air of confidential importance is given the prospectus by a notice printed on the back, which reads: "If this book is lost, kindly mail it to the address below, as it contains matters of importance only to its owner," following which are blank lines for name and address, which the recipient is supposed to fill in as a provision against the unhappy contingency of his dropping the precious document. The officers of the League are A. C. Bidwell, president; William Preiss, treasurer, and C. H. Bowe, secretary. The organization not only has officers, but it has "League colors" which are proclaimed as being "orange and black." The League yell has not yet developed, but will doubtless come out in due time.

How Pennsylvania Piles up Fines.

Whatever may be charged against the State of New Jersey for the high price it sets upon the pastime of motoring within its borders, there is no question that Pennsylvania law, if properly administered may eclipse it. At least, that is the conclusion at which one James Munyon, Jr., of Cynwyd, arrived after a brief sojourn in the town of Abington. After being there only about 5 minutes, he was arrested for violating the automobile law in no less than five different respects. The resulting fine averaged at the rate of something like $11.05 per minute. The bill which Magistrate Williams framed up for him was as follows:

Breaking speed regulation	$25.00
Running without rear light	10.00
Running on wrong license	10.00
Running without blowing horn at crossings	10.00
Costs in the case	2.60
Total amount	$57.60

Buckbee Heads Club of California.

At a meeting of the Automobile Club of California held recently, the following officers were elected for the ensuing year: President, Samuel G. Buckbee; Vice-President, George A. Newhall; treasurer, C. F. Kohl; secretary, L. E. Burks.

WHY CITY CHAUFFEURS ESCAPE

Speeders with "Pulls" Develop Invisibility to Discreet Cops—Police Prefer Fines to Transfers.

In the not distant past a chauffeur in the employ of the municipality was arrested while driving at a high rate of speed a city owned automobile containing the official to whose use the car was assigned. The fact of a city employe being arrested for automobile speeding was not, in itself, of more than passing interest, for though the members of the police department usually "fail to see" a swiftly moving automobile if they know that it is the property of the city, the general subject of the arrest of speed mad chauffeurs is so frequently commented on in the daily press that one arrest more or less excites little or no comment from the public.

The arrest of a municipal chauffeur suggests, however, an interesting question, and the answer to it seems to have been given by the police sergeant who refused to "fail to see" the motor car that was going over the public thoroughfare at a speed which threatened the safety of others who were on the highway.

Though the day when the arrest occurred was the Sabbath, the question that was answered bore no relation to the subject as to what kind of "city business" required the city official's attention at a time when the other members of the department with which he was connected were away from their duties, presumably in their respective homes, but it was the question as to whether or not a city official, i. e., a public servant had rights and privileges which are denied the hoi polloi, and the policeman answered "no."

The reckless, devil may care spirit, with which some of the chauffeurs in the employ of the city disregard speed laws and traffic regulations, has been the cause of many accidents that have cost the taxpayers a pretty penny in damage suits, to say nothing of the increased expense because of the wear and tear on the cars. Yet the disregard for the public safety and the contempt for the authority vested in the traffic police is daily exhibited by the city owned automobiles speeding through the streets, claiming the right of way over all things moving, whether vehicles or pedestrians.

When the municipally owned car, in which the official was a passenger, was halted by the policeman, he at once claimed special privilege and asserted that he was on "city business." The plea had no weight with the officer, nor yet with the magistrate on the following morning when the chauffeur was arraigned, charged with driving at the rate of 27 miles an hour. He was held for Special Sessions in $100 bail.

The city chauffeur, whose series of articles on "Motor Cars as Mediums for Municipal Graft" appeared in the columns of the Motor World not long since, made some interesting statements in connection with this subject when interviewed after the aforementioned arrest.

"While I don't know the details of this special case," he said, "I do know that in my own experience it was seldom that I exceeded the speed limit unless ordered specifically to do so. When I say I did not exceed it, I mean that I did not drive at a speed of over 12 or 15 miles an hour, for, though this is somewhat faster than the law allows, it is by no means reckless driving, and I have yet to see the policeman who considered this rate a violation of the law sufficient to justify an arrest. But it was seldom indeed—unless the night was dark and the company congenial—that my superior did not call for faster and faster speed, and despite my protests, insist on the car being driven anywhere between 20 to 30 miles an hour, even in the busy thoroughfares. I used to protest that I would be arrested. 'Never mind,' he would answer, 'if you're arrested I'll get you out, and maybe he would have done so. I have never doubted but that he'll pay any fine that may be imposed, yet the payment of the fine is not the only thing.

"I don't want the notoriety; I don't want my name in the daily papers; but most of all, I don't want the police department's record of chauffeurs to show against my name or registration number a statement of arrest for speeding. Once arrested and that record will be kept for future reference, and a law abiding individual who may sometimes forget for the moment that he is going too fast, and become a prisoner, will have to suffer, not alone for this, which is really his first offense, but for the other times when he was compelled to speed, by his superior, against his wishes, his judgment and his outspoken protests.

"Last September I read a copy of a letter sent out by the police commissioner to the different department heads, requesting that they keep the speed of their automobiles within the legal limit. I knew that at the time of sending out this letter, the police commissioner sent also an order to his department to make no exceptions in the matter of city machines, but to treat every one, official or private citizen, in the same way; that night I was ordered to 'hit it up' as usual, so I told the inspector of the letter and order, he replied that he had read the former and was not interested in the latter; go ahead.'

"I opened the throttle and let her go. While speeding along I passed one or two policemen who, seeing the department sign on the car, merely turned away, not 'seeing' how fast I was going. Later that night, when I was alone, I met one of the officers whom I knew and asked him why I had not been held up.

"'Well, I'll tell you,' he said. 'The fellow that got your boss his job has got a pull; your boss has got a pull, and if he gets down on me then both of them will use that pull to get me transferred, or something equally disagreeable. Now all of us policemen look at it, that the easiest way is the best way, and we don't see you; that's better than taking chances of getting in trouble. But there's one bad feature in this, too, for if the sergeant sees us let you get past, it means a complaint, but between you and me, I'd rather take a complaint and fine at headquarters than take chances of getting the fellows with a pull after me.'

"And there's the whole thing in a nutshell, the police officers fear results if they antagonize office holders and so they wink at violations of the law when executives with a pull are concerned.

"I might state, in conclusion, that the only city automobiles which are justified in exceeding the speed rules are those of the fire department, and occasionally those of the police department, and to the credit of the latter it must be said that it is seldom one sees a speeding automobile with the letters P. D., N. Y. displayed, unless the machine is being used for the purpose of overtaking some one whom the police desire to apprehend."

New Features of Bay State Law.

Among the several novel provisions of the new Massachusetts automobile law, which will become effective on Sunday next, 12th inst., are one or two which are sufficiently noteworthy to bear comment despite the fact that they were reviewed at the time of the enactment. One of them permits the highway commissions to collect a fee of $2 in addition to the cost of the license for the examination of an applicant. This provision will bear hardest on professional chauffeurs, as they are conpelled to pass an examination in order to secure a license.

Another change from the old law provides that "Wherever on any bridge or way, public or private, there is not an unobstructed view of the road for at least 100 yards, the driver of every vehicle shall keep his vehicle on the right of the middle of the traveled part of the bridge or way, whenever it is safe and practicable so to do." The penalty is a fine of $20 and liability in an action commenced within 12 months of the violation."

Canada Prefers American Cars.

That Canada looks to the "States" for its chief source of motor car supply, despite the enterprise of various Canadian manufacturers and foreign car importers enjoying preferential duties, is evidenced by the registrations in the various provinces. Figures for the period between January first and June first in the province of Ontario are illustrative. Of the total of 205 cars registered in the period, 125 were of American manufacture, not counting fifteen cars the names of which were not supplied, but which were obviously not all non-American.

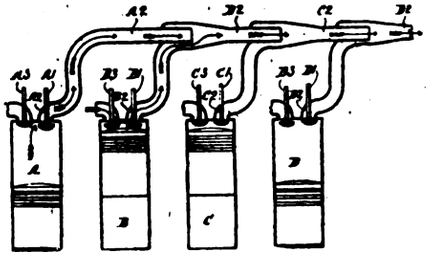
SCAVENGING WITH THE EXHAUST



New and Simple System Adapting the Ejector Principle—Applicable to Either Two or Four Cycle Motors.

Considering the existing universal recognition of the need of effective scavenging of the cylinder of the gas engine, it is somewhat surprising that inventors are not more ready to develop methods of improving the performance of their products by establishing systems of this nature. Of the methods of scavenging which have thus far been proposed, nearly all depend upon an undue amount of mechanical complication. A system has recently been designed in England, however, in which no such complication exists, the clearing of the cylinders of a multi-cylinder motor being effected by the simple expedient of utilizing the exhaust pressure from one cylinder, to clear another by a simple adaptation of the ejector principle.

The system in question is the invention of Messrs. D. Stewart & Co., Ltd., and K. J. McMullen, of London Road Iron Works, Glasgow, N. B. As will be seen from the illustration, the exhaust manifold is so contrived that each exhaust is discharged through a jet, into a relatively small chamber in such a way as to establish the desired ejector effect, while the valve mechanism is similar to that of the ordinary motor except for one important particular, which is to say, the use of a plain, air valve, mechanically operated, and designed to relieve the vacuum created by the ejectors, by admitting air into and through the cylinders. The system, it is to be observed, is applicable to motors of either the two or four-cycle types.

The cycle of action is as follows: As shown in the illustration, cylinder, A, is at the beginning of its exhaust stroke the exhaust valve, A1, being open to permit the discharge of the products of combustion into the "ejector-inductor," A2. Simultaneously, cylinder B, is nearing the end of its stroke, and the effect of the discharge from the nozzle A2 is to create a sharp draught through B, pure air for the purpose, being supplied by the valve, B3, and the discharge occurring through the regular exhaust valve of that cylinder, B1. During the progress of this action, the explosion stroke is just commencing in cylinder, C, and the suction stroke has just been completed in cylinder D. A similar scavenging effect is secured in each of the other cylinders in proper rotation and by the same means.

It will be seen that this system contemplates no alteration of the ordinary working of the motor, whether of the two or four cycle type, the only alterations involved in its use being the insertion of the extra, pure air valve in the cylinder head, and the adoption of the nozzle construction of the exhaust manifold. The cleaning action is induced in each of the cylinders just at the termination of the exhaust stroke, and merely serves to assist the discharge of the spent products of combustion, which thus are replaced with pure air. In consequence, the cylinders are cooled appreciably, the strength of the new charge is sensibly in-

creased by the elimination of the foul remnants of the old charge, and the succeeding impulse obtained is in proportionately cleaner and more rapid action. Although it is not generally recognized, it is true that a successful scavenging cycle, were it attainable without undue mechanical complication, would vastly improve the performance of the average motor.

Blow Torch Minus Pump and Valve.

Both for the road and the shop a good blow torch is frequently an indispensable tool, and many efforts have been made to produce a torch that was at once light and compact, while being simple and efficient. Of these the latest is the "Imp," which has recently been brought out by the Frank Mossberg Co.,of Attleboro, Mass.

The device is entirely automatic in its action, having no pumps or valves, which must be manipulated for its proper oper-

ation. A series of corrugations or "wrinkles" in the neck, as shown in the illustration, increases the heating surface to such an extent that the flame of a match easily generates enough gas to start the torch, after which the peculiar design of the mixing tube makes further attention unnecessary. With four ounces of gasolene the "Imp" will give a powerful, steady, clean blue Bunsen flame for over two hours. The value of such a flame in certain classes of repair work cannot well be over-estimated.

PROBLEMS OE THE GAS TURBINE

Difficulties They Present and Results of Efforts to Meet Them—Dugald Clerk Reviews the Progress Made.

In connection with the rapid commercialization of the steam turbine in the installation of large power plants, the old question as to the possibility of arriving at a proper solution of the problems attending the development of the gas turbine of the internal combustion type is constantly arising. It is only two or three years since Dugald Clerk, the eminent British gas engine expert, declared that from the present standpoint, the gas turbine must be regarded as a practical impossibility. That some of these difficulties are being overcome, and the practicability of this type of motor growing in prospect, is almost a certain consequence of the great amount of energy which is being devoted to it.

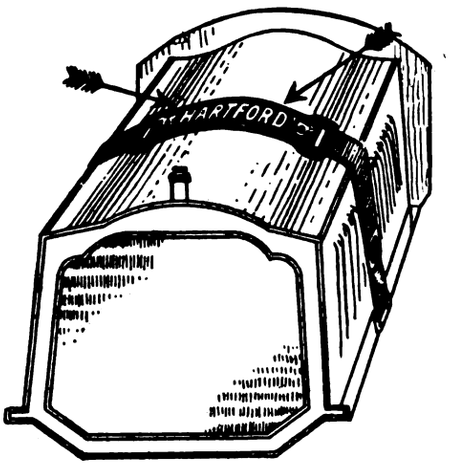
The two chief difficulties which have beset the path of the gas turbine designer hitherto are those arising from the exceedingly high temperatures engendered by burning the gas under compression, and the high speeds necessary between the moving elements in order to secure a proper working efficiency when the gases are being cooled by expansion. In fact these two obstacles alone, are by many engineers considered sufficient in themselves to block the ultimate development of the gas turbine to a point of commercial utility. "The inventor is thus between two horns of a dilemma," says the Electrical Review, in this connection.

"If by expansion he cools his gases to a point where they can be applied satisfactorily for driving the moving parts, they attain speeds far too high for efficient utilization; if, on the other hand, he seeks to reduce the speed by successive expansions of the gases, he obtains in the first stages of this process temperatures too high. One solution of this problem is to lower the temperature of the gases by mixing with them other cooler gases, thus securing a stream of working fluid of greater mass, but lower temperature. In this way both the excessively high temperatures and excessively high velocities may be avoided, but, of course, with a sacrifice in efficiency as stated by the laws of thermo-dynamics.

"One who had aided much in the experimental development of the gas department was M. R. Armengaud, who, before his death, had constructed turbines of this type with outputs up to 300 horsepower. In these the principle just alluded to, of admitting cooler gases to the products of combustion, was utilized. Since his death the work has been carried on by Mr. Alfred Barbezat. The difficulty of finding a material to resist the high temperature reached in the combustion chamber and

Digitized by Google

the erosive action of the hot gases in their passage through the expanding nozzle has been met partially by the use of carborundum. The chamber and the nozzle are lined with this material, and it is backed with a soft packing of asbestos to allow for expansion. When the turbine is in operation this lining becomes sufficiently hot to ignite the fuel as it is forced into the chamber.



"Another problem met in this work was to secure an efficient supply of compressed air. Since the burning of the fuel in the combustion chamber produces a high pressure, both it and the necessary air must be forced into this chamber against this pressure. When a liquid fuel is employed there is not much difficulty, but it is more troublesome to supply the necessary air, and when an excess of air is used in order to lower the temperature of the issuing gases, additional work is thrown upon the compressor. The compressor now in use is of the multiple turbine type designed by Rateau, it being thought that, since in a turbine the object was to get away from reciprocating mechanisms, the use of a reciprocating air compressor would be absurd, as a complete turbine unit should consist of rotary mechanisms only. . . . .

"The efficiency obtained by the latest machines, which were rated at about 300 horsepower, is said, by Mr. Barbezat, to be not so high as that of reciprocating gas engines. It is to be regretted that he could not give definite figures; but these are promised later. This statement has no reflection upon the gas turbine and merely indicates its present stage of development. Better results may be expected, and some of the losses now taking place will be avoided. It is interesting to note one method at present adopted for this purpose. It has been found necessary to cool, by means of water jackets, the combustion chamber and the expansion nozzle and perhaps other portions of the turbine. The water thus heated is forced into the combustion chamber, where it is converted into steam, with a consequent lowering of the temperature of the driving gases, and thus lightening the work of the air-compressor, which otherwise would be required to supply a much larger volume of air.

"Perhaps one of the greatest drawbacks to this type of prime mover is, what may be called by analogy, its low power-factor. This is due to the necessity for an air compressor which absorbs about half the total power of the turbine proper. That is to say, a gas turbine with an output of 300 horsepower actually develops about 600, 300 of which is necessary to drive the compressor. This 300 horsepower, utilized by the compressor is not, of course, lost. It is merely negative work in the compressor and positive work in the turbine. It represents, as it were, 50 per cent. of the total power of the turbine circulating between it and the compressor, neglecting, of course, losses; and consequently the turbine itself has but half the rating it would have were not this condition present."

Anti-Rattling Device for the Hood.

No one characteristic of the advancement which has been made in automobile development is more pronounced than the elimination of noise. In the not distant past the progress of a motor car was marked by much the same discordant sounds that still are associated with trolley cars to which the former added the noise of an unbridled exhaust. But, so far as automobiles are concerned, the rattle of machinery is

largely disappearing. With many machines, however, the rattling of the hood still is a source of annoyance, which it has been found difficult to overcome. A novel method of overcoming this objectionable noise is found in the Hartford Hood Anti-Rattlers, a simple little device made by the Hartford Rubber Works Co., Hartford, Conn.

This latest comer in the accessory field is nothing more or less than a strip of flexible rubber about a foot in length, a couple of inches in width, and perhaps a quarter of an inch in thickness; adapted to be placed over the hood, and slotted at either end to receive the usual hood strap. When the anti rattler is placed over the center of the hood and the retaining straps drawn tight and buckled firmly, the rubber strip is stretched slightly and through its elasticity, thestraps are kept in constant tension. The hood thus is held in place and with the rubber takingup the vibration, the noise is deadened and wear and tear due to the usual vibration, practically eliminated.

Having a Proper Place for Everything.

Nowhere does the old maxim of "have a place for everything and have everything in its place," better apply than to drivers of automobiles. Tools should be kept by themselves in receptacles that will not permit of their rattling together. Oil cans should be clean on the outside and away from everything else; spare tubes should be so placed that they will suffer no damage from coming in contact with hard substances or grease of any description, and spare parts, such as valves, nuts and cotter pins, should not be thrown together, but kept separately in a small box or drawer in which they may be placed in partitioned spaces, where they readily may be found, and until needed will be safe from injury.

Selecting the Suitable Spark Plug.

In the selection of a suitable spark plug, motorists should bear in mind that the physical construction of the motor plays an important part in relation to the plug's efficiency when in the cylinder. The distance between the explosion chamber and the outside of the cylinder is a factor which has to be considered in the proper selection of a plug, for unless the sparking points are so arranged that they are even with or slightly beyond the pocket so as to project into the cylinder, the spark plug opening forms a recess in which spent gas may accumulate and delay the force of the explosion owing to the fact of the spark occuring at a point where the fresh charge is not in contact with the points. Of course, the greatest care also should be exercised to select a plug no part of which can possibly come in contact with the piston.

Importance of "Lining up" on the Car.

Too much stress cannot be put upon the subject of the importance of a proper "lining up" of the power plant and transmission of a car. If the action or sound of the mechanism denotes that there is something amiss, unless the trouble is located elsewhere it always is well to look to the general alignment of parts. If an owner cannot attend to this matter himself or if his chauffeur cannot, it is advisable to have an inspection made by some one who is competent to make it, and it is far better to lay up a car that is out of line until the evil can be remedied than to continue to use it to the probabble destruction of many of its component parts.

Periodical Inspection of the Underpan.

Cars which are equipped with metallic under-pans for protecting the mechanism should be subjected to rigid, periodical inspection in the parts so concealed and not readily accessible from above. The pan prevents loose and projecting bolts or other parts from being seen, and furthermore, requires the occasional cleaning which this ensures. Incidentally if the pan happens to be loose or broken, the fault will be revealed.

While "racing" the engine just prior to cutting out the spark permits of starting again under compression, thereby saving some slight labor to the driver, the practice is a pernicious one. The wear and tear on various parts of an engine that is being run in this way, at high speed and with no load, is considerable and while the practice is a common one, indulgence in it is not a sign of a cautious driver.

DISCLAIMS POLICE AUTHORITY

Commissioner Smith of New Jersey Explains His Limitations—Local Authorities Must Police Their Roads.

That the Department of Motor Vehicles of the State of New Jersey is powerless to prevent the speeding of automobiles by doing police duty, is the latest pronouncement of Commissioner J. B. R. Smith. In response to a complaint sent to him by the Freeholders of the Mercer county board, to the effect that the excessive speeding of the machines was damaging the roads of the county, and requesting the department to intervene, the Commissioner responded to this effect, stating that the policing function must be performed by the local authorities.

"I beg to assure you that the department has suppressed and will continue, to the extent of its ability and within the scope of the powers vested in it by law to suppress the abuses attending the uses of motor vehicles," says Commissioner Smith. "Your committee, however, seems to have overlooked the fact that the law places the burden of policing the roads upon the municipal and county authorities. Our State does not undertake to preserve the peace of the different localities except, of course, in those special cases where the aid of the militia becomes necessary; and while the limited number of inspectors (there being only ten paid inspectors for the whole State) appointed under the motor vehicle law are vested with the power to arrest for motor vehicle violation, their duties, primarily, are to advise and to co-operate with the local police establishments and county officers, for the purpose of securing uniformity of action, to investigate complaints of violations of the law made to the department and report their findings for the purpose of determining whether licenses should be revoked; and to investigate with reference to the compliance with the law regarding the carrying of identification marks and certificates.

"Of course it would be absurd to assume that a statute which provides for only ten persons for the whole State vested with the power of arrest, should direct that they should be charged with the entire duty of enforcing the speed regulations pertaining to motor vehicles.

"We are without power, however, even if we desired to do so, to usurp the functions of the county and municipal authorities."

Identification Marks for Jersey Cars.

Identification marks for automobiles registered in New Jersey, to differentiate those carrying unexpired licenses under the old law and those registered under the amended statute, have been provided by J. B. R Smith, State Motor Vehicle Commissioner. The commissioner says that all cars whose registrations expire before December 31 shall carry the metallic elliptical disc containing the certificate of the department regarding the manufacturer's number affxed to any marker which was legal at the time the amendments to the law became effective. Those whose registrations will expire on December 31 or later shall carry the blue marker with the official seal, containing the manufacturer's number of the car affixed. This course is in keeping with the provisions of the new law and all motor vehicle owners failing to carry one or the other of these official identification marks will be liable to a fine.

Jersey Magistrate Reverses Himself.

Refusing to accept the uncorroborated statements of a lone constable who alleged that Leonard Paulson, of Summit, N. J., had operated a motor car at a speed greater than 20 miles an hour, Justice Woodruff, of New Providence, discharged the defendant after the latter had brought forward, as witnesses, the occupants of the car, who testified that the machine was equipped with a speedometer and that at the time in question the instrument recorded but 15 miles an hour. Incidentally the justice reversed his own decision in the case, rendered at the time of the arrest, when he found the prisoner guilty and imposed a fine. Paulson promptly refused to pay, and demanded a trial, with the above result. He also contended that one man could not properly take any reasonably accurate measurement of the time and this contention was given weight by the justice.

Automobiles for Military Baggage Train.

When the Fifth Regiment, National Guard of New Jersey, goes into camp at Sea Girt on July 25th a new departure will be made in the transportation of the baggage to the encampment. Automobiles will be employed and the camp orders issued announce that the vehicles will leave Paterson, Passaic, Englewood, Hackensack, Leonia and Rutherford at stated times on the morning of July 25. As they will run on schedule time, the baggage must be ready for transportation at the armories when the motor cars arrive. Two enlisted men will be permitted to accompany each company's baggage.

United in the Good Roads Cause.

Teamsters have joined forces with the automobilists in Minneapolis to secure road improvement. The Minneapolis Teamsters' Union and the Minneapolis Automobile Club have decided to go into politics to secure good highways. The plan is to work and vote only for aldermanic candidates who will pledge their aid to the good roads cause. Theodore Wirth, superintendent of the Minneapolis parks, has been elected the first honorary member of the automobile club and it is expected that his official position will enable him to give material aid to the movement.

BAY STATE ROAD EXPERIMENTS

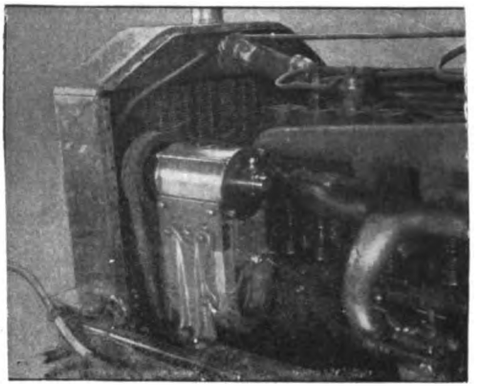
Trying Processes for Making Highways Durable and Dustless — Interesting Work Begun at Cape Cod.

Massachusetts is prolific in experiments in the direction of preserving roads and abating the dust evil. In the city of Marlboro two contracts have been made with concerns making coal tar preparations, one firm applying the tar after heating it and the other applying it while cold. The stone road is first swept, then a thin tar is sprinkled on and brushed into the surface, after which the sweepings are put back to form the wearing surface.

Another experiment is about to be made by the highway commission in the town of Hamilton. Contracts have been awarded for building a dustless stretch of road. It is planned to tear up a stretch of much traveled highway and to build it over again from the bottom to the top. The bottom course will be laid, as in an ordinary macadam road, of stone crushed to the proper size, which will be rolled down hard. On top of this a layer of stone that has been treated with tar will be laid to a depth of two inches. This will be spread and then rolled solid, the top to be sprinkled with a thin layer of tar. It is not planned to build a tar concrete road, but rather a stone road with enough tar to bind the material together and assure a smooth, hard and dustless surface.

Still another experiment is about to be made by the commission on Cape Cod, where there is no stone to speak of, so that the road must be constructed entirely of sand. A heavy grade of Texas crude oil, containing a large percentage of asphalt, will be used with the sand. The sand road will first be shaped with a road machine, and heated oil will be spread over the surface. A second lot of oil will be sprinkled on when the first coat has been on for two weeks. The surface will then be cut up with a disc harrow so as to mix the sand and oil to a depth of four inches. After this has been done the road will be rolled and the surface sprinkled with a thin layer of sand to absorb the surface oil.

A little work of this sort was done under the highway commission's supervision about two years ago, which has resulted so satisfactorily that the State road officials have decided to adopt the plan for roads on Cape Cod, where there is no material with which to construct stone roads. The stretch treated in this manner two years ago has withstood wear better than had been expected and the treatment resulted in a good, firm roadway.



"The A B C of Electricity." Price, 50c. The Motor World Publishing Co., 154 Nassau Street, New York City.

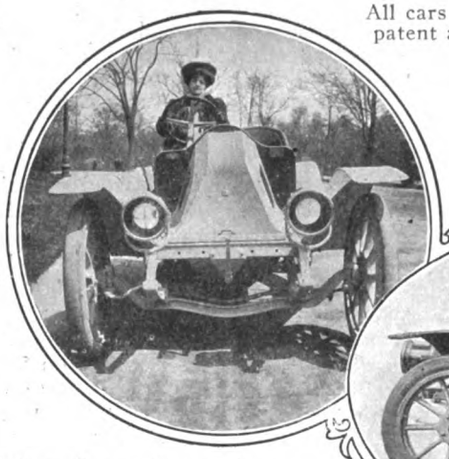
New Magneto Adapted to Fords.

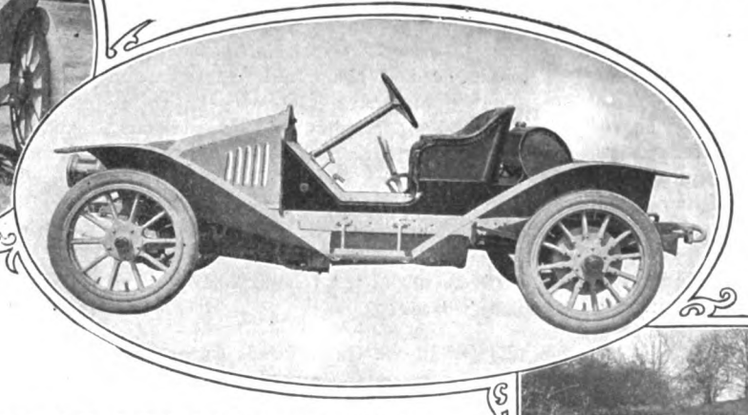
Because of the danger of obtaining an injurious combination of windings in magneto and coil, owners who contemplate installing a device of the former type on cars which are not primarily designed for its use, should be extremely cautious about making the investment. In case the windings of the magneto armature and those of the coil are out of proportion to one another—which is perhaps the simplest way of expressing non-technically a condition which is apt to provoke irregular running and expensive upkeep—no little trouble is likely to ensue. In this connection, owners of Ford runabouts who incline to the use of the magneto are provided with an equipment especially designed for the purpose, in the new "Model F," K-W magneto, which the K-W Ignition Co., Cleveland, O., produces along with eight other types of magneto, not to mention several other varieties of ignition specialties.

Not simply is this apparatus designed to "balance" the windings of the coil regularly installed in the Ford cars, so that its performance will be non-injurious to the original equipment, but it also is contrived in such a way mechanically, that it may be readily attached to the frame of the machine, and driven by means of a belt, from

the fly wheel. The bracket upon which it is mounted is regularly furnished with it. A special non-stretchable belt also may be obtained for driving purposes, at a slight advance in the price. The manufacturers guarantee the magneto to start the engine easily without the use of the batteries, and claim in addition, that because of the hot spark which it develops it will run the engine faster and better, and with better fuel economy, than as a general thing, would be possible with the battery equipment alone.



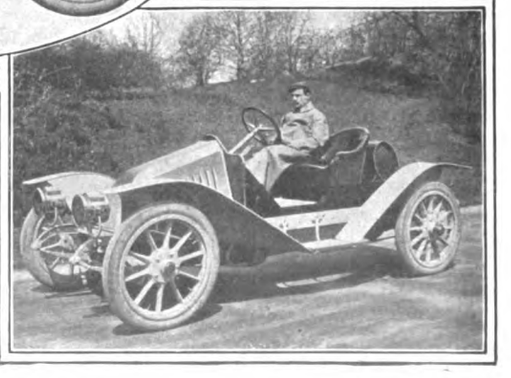
Anti-Scale Compound for Cooling System.



Like boiler compounds for preventing scaling, preparations intended either to prevent or remove deposits of foreign matter and scale from the interior of the cooling system of the automobile are likely to furnish an ample field for the activities of the purveyors of motorist's supplies for some little time to come. Quite the latest of these is a British innovation, known as "Evaporine," which is mingled with the water in certan fixed proportions, and in the course of time tends to remove all incrustations of an injurious nature. Needless to say, the careful motorist will find it a matter of economy to use only pure water in the radiator, in which case, as there is little or no deposit, no such compound is at all necessary.

PALMER-SINGER

All cars sold by us are licensed under Selden patent and guaranteed for one year.



Palmer-Singer Six-Sixty Runabout, 6 Cylinders, 60 H. P., $2,850
Palmer-Singer Town and Country Car, 28-30 H. P., $3,000
Palmer-Singer Six-Fifty Racing Car, 6 Cylinders, 50 H. P., $2,450
Palmer-Singer Four-Forty Seven Passenger Touring Car, 40 H. P., $4,000

28-30 H. P.
4 cylinders
Price, fully equipped,
$1,950

We show here three views of the Palmer-Singer "Skimabout" or Four-Thirty.

Nickel steel throughout. Imported F. & S. ball bearings exclusively. Bosch high tension magnetos and multiple disc clutches in all models. Nickel steel frames. Drop forged I beam, nickel steel front axle—four-speed selective type, sliding gear transmissions with direct drive on third speed. All brakes equalized, all expanding type and on rear wheels. Universal joints on all steering connections. All types shaft-driven, all moving parts inclosed in dustproof cases.

The Week's Patents.

885,960. Vehicle Wheel Rim. Edwin C. Shaw, Akron, Ohio, assignor to B. F. Goodrich Company, Akron, Ohio, a Corporation of Ohio. Filed Feb. 20, 1907. Serial No. 358,463.

1. A vehicle wheel rim comprising a channel iron carrying one permanent tire flange, a removable split ring carrying an opposing tire flange, downwardly extending lugs upon the split ring, near its terminals, slots in said channel-iron adapted to receive the said lugs, a lip or lug extending upwardly from the channel-iron, and a key adapted to pass through said upwardly extending lip and through mutually registering grooves in the contacting surfaces of the ring terminals.

885,986. Transmission Gear for Motor Vehicles. Leonard H. Dyer, New York, N. Y. Filed Jan. 22, 1906. Serial No. 297,116.

1. In a transmission gear for automobiles, the combination of a driving member, a driven member, a driving gear for the former, a plurality of intermediate gears, including a reversing gear, and means, including mechanism shiftable as an entirety, for driving said driven member through any one of said intermediate gears.

886,016. Automobile Radiator. Charles Schmidt, Cleveland, Ohio, assignor to The Peerless Motor Car Company, Cleveland, Ohio, a Corporation of West Virginia. Filed Nov. 18, 1907. Serial No. 402,637.

1. In an automobile radiator, the combination of an upper tank having outlets through its bottom near its sides, a lower tank having inlets through it top near its sides, side members secured to said two tanks inside of said inlet and outlet openings, rows of horizontal tubes extending between and passing through said side members and secured thereto, return bend plates secured to said side members and covering a plurality of rows of tubes, and cover plates secured to the bottom of the upper tank and to the top of the lower tank outside of said openings therein, and secured at its side edges to said side members.

886,019. Rim for Motor Car Wheels. Don C. Smith and William F. Gorton, Muncie, Ind. Filed Oct. 10, 1906. Serial No. 338,214.

1. The combination with a wheel having a rigidly secured felly rim thereon, of a tire-retaining rim comprising oppositely disposed annular rings having in-turned flanges ta their outer edges, this vertical facing being provided with a rabbeted joint having the seat thereof beveled, the vertical line of jointure of the facing edges of the rings being to one side of a line central between the flanges, there being transverse apertures provided in the rings and having bolts therein whereby the members many be secured togethere, the inner surface of the tire-retaining rim being machined to fit the felly rim, and transverse apertures being provided at intervals at the line of jointure of the tire-retaining rim and the felly rim and having bolts therein whereby the tire-retaining rim, in assembled form, may be secured to the wheel, substantially as described.

886,098, Motor Vehicle. William W. Wainwright, Connersville, Ind. Filed Mar. 7, 1907. Serial No. 361,089.

1. In a motor vehicle, the combination of a hollow steering axle structure, a pair of live shafts mounted in said structure and connected at their inner ends by a compensating gear also mounted within the structure, a driving pinion structure journaled within the hollow axle-structure and meshing with the compensating gear, a frame yoke pivotally mounted exteriorly upon the axle-structure on an axis at right angles to the axis of the axle-structure, a driving shaft journaled in said yoke, a pinion meshing with the driving pinion structure, the axle structure having a substantially horizontal opening permitting the engagement of the driving shaft pinion with the driving pinion structure, and means for swinging said axle structure in the yoke upon the pivotal connection therebetween.

886,103. Hydrocarbon Burner. Rollin H. White, Cleveland, Ohio, assignor to The White Sewing Machine Company, Cleveland, Ohio, a Corporation of Ohio. Filed Feb. 24, 1903. Serial No. 144,557.

1. The combination of a main burner having a mixing tube, a casing above the main burner and inclosing the combustion chamber, a sub-burner which extends up through the main burner, a vaporizer removably supported within said combustion chamber and extending over the sub-burner and over a part of the main burner, and a support for said vaporizer within the combustion chamber, with a feed pipe, a valve casing secured to said feed pipe, a vaporizer feed pipe which extends through a hole in the wall of the combustion chamber and separably connects the vaporizer with said valve casing, a valveless pipe connected with the discharge end of the vaporizer and extended out through the same hole in the wall of the combustion chamber and terminating in a nozzle which discharges into said mixing tube, and an independent feed pipe for said sub-burner, substantially as specified.

886,191. Variable Speed Power Transmission Device. David M. Dearing, Jackson, Mich. Filed Feb. 15, 1906, Serial No. 301,282. Renewed April 1, 1907. Serial No. 365,856.

1. A transmission gearing, including a driving shaft, a driven shaft arranged at substantially right angles to the driving shaft, a beveled frictional wheel having a bevel pinion fixed to the driven shaft, and a beveled friction wheel having a bevel pinion fixed to the driving shaft adapted to successively engage with the wheel and pinion carried by the driven shaft.

886,225. Current Distributing Device for Igniting Explosive Engines. Henri de la Valette, Paris, France. Filed May 8, 1906. Serial No. 315,769.

1. A high tension current distributing device, comprising a plate of insulating material, a lid of insulating material on the plate, a revolving disc of insulating material located between the plate and the lid, contact pieces arranged in a circle in the plate, a contact ring located in the lid, and a brush located within the revolving disc, adapted to ride on one side on the said contact pieces and on the other side on the said contact ring.

886,265. Rapid Fire Carburetter. James A. Speed, Los Angeles, Cal., assignor to Speed Manufacturing Company, Los Angeles, Cal., a Corporation of California. Filed April 25, 1907. Serial No. 370,324.

1. In a carburetter, a strangling tube, means for spraying gasolene into the strangling tube comprising a nozzle in the tube, a valve at the upper end of the nozzle, an upper stem on said valve, a lower stem on said valve projecting into said nozzle, a guide in the nozzle in which the lower stem slides, means for admitting air to the strangling tube to combine with the spray of gasolene, auxiliary means for admitting a fur-

WANTS AND FOR SALE.

15 cents per line of seven words, cash with order. In capitals, 25 cents per line.

FOR SALE—1908 Model G Marmon touring car, 35-40 H. P.; as good as new. Full equipment, including top, etc. Reason for selling, owner has ordered a larger and more powerful car of the same make. BRAZIER AUTOMOBILE WORKS, 38th and Market Sts., Philadelphia, Pa.

AUTOMOBILE TIRES — Overstocked with second-hand casings and tubes, all sizes, right prices; tire repairing, recovering, rebuilding; best workmanship and material. All work done on short notice. Tel., Harrisson 7301. BEBBER & COEN, 331 Michigan Ave., Chicago, Ill.

CORBIN Touring Cars and Runabouts, $800 and up. Thoroughly overhauled by us and guaranteed. CORBIN MOTOR VEHICLE CORP'N OF N. Y., 1888 Broadway, near 62d St.

FOR SALE—$100 to $500 saved. Buy a good second hand car now for next season. Write me to see how much I can save you on others' sacrifice prices. Light touring cars and roadsters, including Thomas, Pierce, Packard and Peerless, and other standard makes from $640 to $1,680. C. T. PAXTON, 1200 Niagara St., Buffalo, N. Y.

The Oil You Can Feel At the Crank

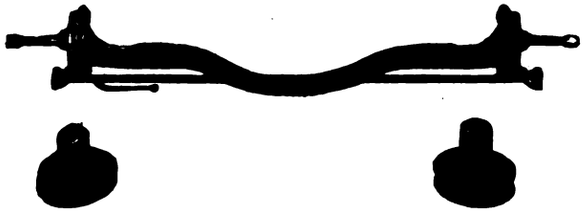
The slightest "feel" of the crank proves the perfection of MOBILOIL. There is no possibility of anything but perfect lubrication in any gasoline engine, regardless of type. For different machines there are different grades of

VACUUM

MOBILOIL

Our booklet tells you which is the proper grade for *your* automobile—and why. A copy will be sent free on request. It contains much of interest to motorists.

MOBILOIL in barrels, and in cans with patent pouring spout, is sold by all dealers. Manufactured by



VACUUM OIL COMPANY
Rochester, N. Y.

NEW YORK GEAR WORKS.
56 GREENPOINT AVE., BROOKLYN, N. Y.

Nuts That Require Tightening After considerable use the bolts holding the sprocket rings to the driving wheels of chain driven cars tend to become loosened in the spokes. Hence, when overhauling an old car, it is well to tighten the nuts which hold them in place, riveting over the ends for the sake of security. In doing this care should be taken not to throw the sprocket out of line.—From "Motor World," August 8, '07.

1909 FOUR-CYLINDER

Stevens-Duryea

MODEL X

In bringing out this new model we do not in any way retract any claims that we have made for the six-cylinder car which we are firmly convinced is the highest type of automobile construction. In response to a demand for a larger and roomier car than our twenty horsepower four-cylinder Model R, and more moderate in price than our Light Six, we have produced the Model X. This model supplies a demand for a four-cylinder car a little larger and more powerful than the Model R, which has been discontinued. The owner of the Model X can feel that the well-known features of the Model R are embodied in his car, together with the advantages of more room and power. In brief, the Model X is an enlargement and refinement of the Model R, representing the most advanced ideas in automobile designs, together with Stevens-Duryea construction and workmanship, which have been proven absolutely correct.

The Unit Power Plant
AND
Three-Point Support

This construction, which has made the name "Stevens-Duryea" synonymous with motor car efficiency, is retained. Stevens-Duryea cars were built on correct principles in the beginning, and at no time have any radical changes been made in their design.

Large Sales

make it possible for us to import **THE CELEBRATED BRAMPTON CHAINS** from **ENGLAND** (paying freight and duty), and sell them at the same price at which the several other automobile chains are sold to manufacturers, jobbers, dealers and users.

THE BRAMPTON MOTOR CHAIN

All side plates on both sides on the Brampton Chain are stamped **"BRAMPTON."**

LARGE SALES and SMALL PROFIT with thousands of satisfied customers is our best advertisement.

THE BRAMPTON CHAIN is made of helf-hardening Steel; the strongest Chain in the World. All parts polished; fits sprockets (that are properly cut) without friction.

Some of the other chains may look like **THE CELEBRATED BRAMPTON CHAIN** because some of the other chain makers began to copy the design and shape of the **BRAMPTON CHAIN** links in 1904. They have improved somewhat on their copied design from time to time until these chains now look more like the **BRAMPTON CHAIN** than ever before. These chains somewhat resemble the **BRAMPTON** in appearance, but the manufacturers of such chains have been unable to copy the material—self-hardening steel.

NO CHANGE IN THE BRAMPTON

There has been no change in the design, construction, material or finish of the **BRAMPTON MOTOR CHAIN** in the past ten years.—**"ENUF SED."**

PRICE

The price being equal, it's presumable you want the best, and full value for your money. In such cases, the **BRAMPTON FILLS THE BILL,** and the prices are the same to manufacturers, jobbers, dealers and consumers as any other chain of equal size—as follows:

CHAINS TO FIT AMERICAN CARS

1 x ⅜ x 9-16—1 x ½ x ⅝—1 x ½ x 9-16 roller	$1.00 per foot.
1 x ⅝ x ⅝ roller	1.17 "
1¼ x ½ x ⅝—1¼ x ⅝ x ⅝—1¼ x ⅝ x ¾ roller	1.25 "

We also carry in stock the **BRAMPTON CHAINS** to fit Foreign Cars—Mercedes, Panhard, Martini, Fiat, etc.

Your 1908 Car

You can have the new car that you order fitted with the **CELEBRATED BRAMPTON CHAIN** if you order it that way. No extra cost to either you or the manufacturer. All standard sizes in stock to fit American and Foreign Cars at the same price as the other chains.

SPECIAL CHAINS TO FIT THE INDIAN MOTORCYCLE.

Agents wanted in unoccupied territory. Catalog on request.

We are Sole American Agents for **BRAMPTON CHAINS,** and they cannot be bought from anyone else except through our Agents.

Pan-American Automobile Body Polish

Pan-American Polish was awarded the Bronze Medal at the Louisiana Purchase Exposition at St. Louis, 1904. This polish has been carefully prepared for the Automobile trade. It is also applicable to the carriage trade, or can be used on any varnished furniture or woodwork of any kind. It will remove stains, cover scratches; leaves the automobile with its original new lustre, without being sticky or greasy. Furnished in eight-ounce bottles. Guaranteed not to harm the finest varnish. For sale by all Automobile Dealers. Price 60 cents per bottle.

The Miller Automobile Jack

The Miller Automobile Jack is a quick acting, automatic lowering jack, designed especially for automobile use, and is adapted to the factory or garage as well as to be carried as a part of the equipment on motor cars. It is high-grade and one of the finest finished jacks on the market. We guarantee this jack for twelve months. The list price of the Miller Jack, $3.50 each.

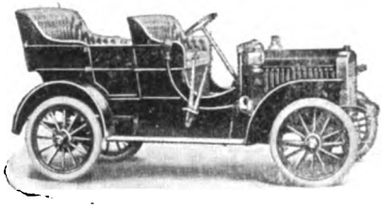
$2,500 Challenge!

The "Maxwell"

Challenges the Glidden Tour Winner for an Endurance Run from New York to San Francisco

THE WHY—We have been enthusiastic supporters of the Glidden Tour. In the first one our $1450 car tied the winner, a $3000 car. In the second, a Maxwell won the Deming Trophy. Again, a Maxwell runabout was the only one of all pilot cars to complete the tour. One identical Maxwell competed in every Glidden Tour and is still running as good as ever. We competed in these Tours



BECAUSE they gave a chance to show publicly that Maxwell cars are superior in many ways to high-priced automobiles.

INFLUENCED by a spirit of trade jealousy of the Maxwell and its many triumphs over them, the Glidden-Tour Rules have been so modified as to let the high-priced cars down easy if they lose.

HOW RIDICULOUS to expect us to enter a contest in which the losing high-priced car can minimize or excuse defeat by pointing to a schedule which made its running time 30 to 45 minutes faster a day.

IT IS

Not an experiment
Not an assembled car
Not a slavish copy of foreign design

BUT

A genuine American
For American roads and American touring conditions

The Maxwell Challenger—Model D, 4-Cylinder—24-30 H. P.—Price $1750

Three-point suspension, multiple-disc clutch, unit construction, thermo-syphon cooling are original in the Maxwell
All others who use them pay the Maxwell the sincere compliment of imitation.

10,116 MAXWELL OWNERS testify that they have as good a car at $825, $1450, or $1750 as they would possess had they paid at least twice the Maxwell's price.

WE ARE WILLING TO PROVE IT hence we challenge the winner of the Glidden Tour to an endurance run from New York to San Francisco, under Glidden Tour Rules of 1907, which put us on equal terms with the highest-priced and most powerful touring cars made. Winner to dispose of $5000 purse.

Glidden Tour An Auto-Meter Parade

It was a walk-over. The men who put their best efforts into making cars for this big event knew what speed indicator to buy—for every Warner used in this event was purchased and we can show the official order.

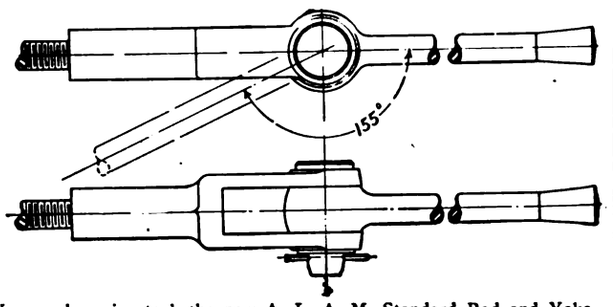
This big Warner percentage is a mighty potent fact. The 1908 Glidden Tour was a manufacturers' battle-ground—a struggle for blood. Every firm put out its best product and its best driver. None but the best of accessories were considered for a moment. Not a detail was overlooked that could in the least contribute to the possible winning of the famous trophy. No manufacturer who is out to make a record—amid company he dare not think of despising—would make the fatal mistake of using an accessory that is liable to fall down on him. He will scrutinize. He will investigate. He will rigidly try out everything that goes to make up his equipment. Naturally he is going to use that which proves to be the best.

A Warner Walk-over

57 Entrants
36 of them Warner-equipped
63 PER CENT. OF THE WHOLE

When manufacturers will turn down instruments that have been offered to them as gifts and pay out their good coin for Warner Auto-Meters, there must be something in it when we say that we make the only speed indicator on earth. This proves the supremacy of the Magnetic Principle—for manufacturers are discerning men.

That which is good enough for the Glidden Tour entrants is surely good enough for you.



And you don't have to pay out one cent to try one of them, either. We'll put an Auto-Meter on any car on earth for a 30 day trial—no deposit—no agreement. Nothing but your promise to give the Auto-Meter a fair trial.

Write us to-day and ask us to send you one. Just tell us the make, year and model of your car with size of wheels and tires. You'll get one by express prepaid. If it doesn't suit you, return it at our expense. There will be no argument.

You *Can* Afford the $2000 Mitchell

—Afford to *buy* it because it is moderate in price.

We know you can afford to *keep* it, because we have many letters from users of Mitchell, testifying from actual daily experience, that it is the most economical car to *operate*. Before *you* buy a car, send for these letters and try a Mitchell in a 50 or 100-mile road test.

In demonstration, you'll notice not only that its style, finish and construction is equal to that of the extravagantly high priced cars, but that its *performance is too.*

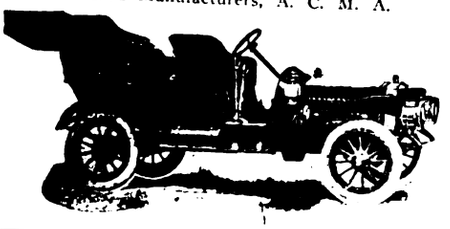
Proof is easy, Mr. Business Man.

The Mitchell Agent will be glad to take you out at any time you say. Just call him up—no obligation on your part.

Try the $2000 Touring Car—the $2800 Limousine—the $1250 Roadster or the $1000 Runabout.

Get demonstrations of high priced cars and compare the Mitchell with them.

Call up the Mitchell Agent today and just say



"*Show Me*"

The Mitchell Touring Car shown below is 35 H. P.—4-cylinder—speed, 50 miles—finish, Mitchell blue—price, $2000.

Write for Catalogue No. 18, describing the other Mitchell models.

THE INCOMPARABLE WHITE

THE CAR FOR SERVICE

Write for White Bulletin No. 15

The above illustration is reproduced from the new White Bulletin No. 15, an attractive little booklet devoted to some of the more important automobile events of the last few months. The leading articles are "The New Road Record Between San Francisco and Los Angeles," "The Fort George Hill Climb," "The Quaker City Reliability Contest" and "The Harrisburg Reliability Contest." In addition to these four detailed accounts of White victories, brief space is given to the numerous minor contests in which the White has carried off first honors; also, the activities of private owners of White cars and the doings of "Government White Steamers" in this and other countries receive attention. We believe that you will find this booklet of interest.

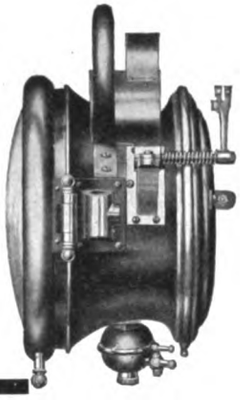
SOLARCLIPSE
LAMPS



TWO DISTINCT FIELDS OF LIGHT

The last and final move forward toward perfecting a lamp for automobile use—the

SOLARCLIPSE

scientifically solves the lighting problem. These lamps illuminate the road with two distinct fields of light; one long and one short distance ray.

The Automatic Self-Eclipsing mechanism which operates from the dash through means of a lever makes it possible to cut out the long distance ray at will. The long distance ray projected by Solarclipse Lamps penetrates the darkness for one thousand feet ahead. The short distance ray is thrown directly in front of the car.

Complete description of the Solarclipse Lamp and Besnard System of Lighting in our 1908 catalogue. Sent free upon request.

THE BEST BATTERY
IS THE
WITHERBEE

It is used and recommended by practically all the leading manufacturers and dealers. This fact in itself is an acknowledgment that there is no better storage battery to be had. From the standpoint of material, design and workmanship—it is impossible to construct a better battery. On any car the Witherbee means perfect, efficient ignition, reliable at all times, under any conditions.

If desired Agents and Branches of this Company will fulfill any requirements of manufacturers, dealers and owners

It is the uniformly satisfactory manner in which Morgan & Wright Tires stand up under any kind of service, from a Glidden Tour to a trip "downtown" and back, that makes them the ideal equipment for the motorist who uses his car under a variety of conditions.

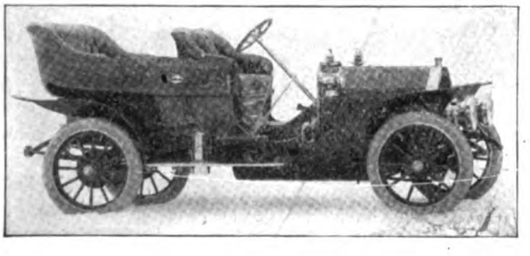
Here's the way they stood up under one test—a 50-mile race—at Los Angeles, Cal.:

"The Model 'G' Cadillac entered by us in the fifty-mile race at Agricultural Park, on May 30th, was equipped with Morgan & Wright tires, and made a most creditable showing in this race. These tires showed very little wear as a result of their fifty miles hard usage in the race, and after the race were still good for several thousand miles of ordinary service, notwithstanding that they had been used some sixty-seven miles on the car in the try-out. In fact, the remarkably good service they gave was one of the features of the 'race meet,' and, of course, contributed most materially to the success of the car.

"We are also pleased to state that your tires made equally as good a record on the Cadillac in the one hundred-mile race the following day.

"Yours very truly,
"LEE MOTOR CAR CO.,
"D. M. Lee, Mgr."

Every Morgan & Wright Tire has that same ability to give troubleless service, whether it is used in racing, touring or city driving.



That ability will be at your service if you specify them on your car.

MORGAN & WRIGHT, Detroit

Branches, Agencies or Dealers Everywhere

THE REASONS WHY

The manufacturers of high grade automobiles equip their best cars with **Timken Roller Bearings and Axles** are—that the principle on which

BUICK MODEL 5—Winner of Indianapolis Automobile Trade Association Sealed Bonnet Contest. Equipped complete with TIMKEN ROLLER BEARINGS AND AXLES.

TIMKEN ROLLER BEARINGS

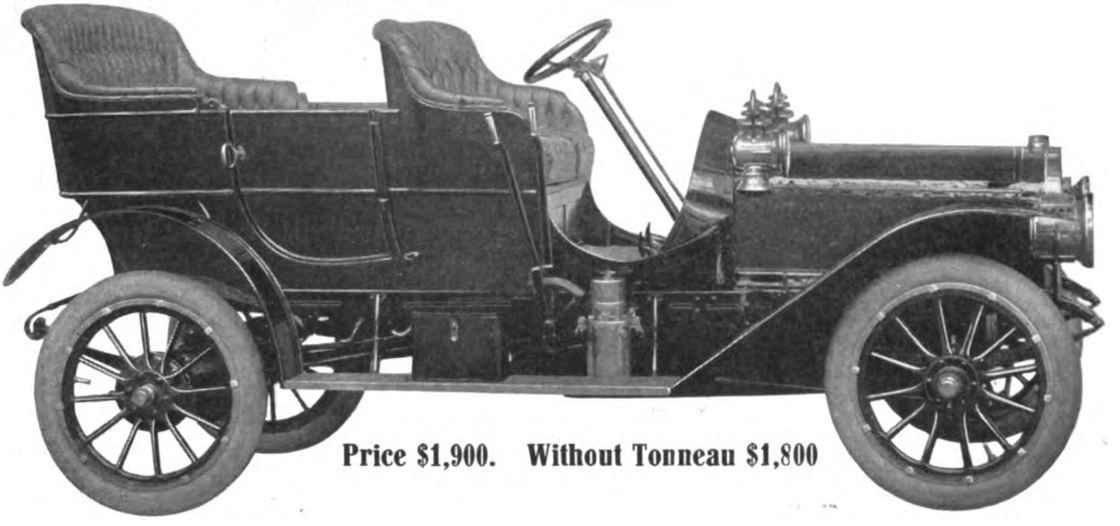
are built, is the only one by which the friction loss is reduced to one-quarter of one percent or less—that provides the maximum bearing capacity in a smaller diameter than any other type and that takes up loss through wear without changing its characteristics.

Timken Principle and Timken Quality

are in consequence, the accepted standards of efficiency in anti-friction bearings.

Comparative tests under actual service conditions will prove that a lightly built car equipped with

TIMKEN ROLLER BEARINGS AND AXLES



has greater endurance and stress resisting qualities than mere weight and strength of metal can give it. Descriptive literature and special information gladly supplied.

THE MOTOR WORLD

Volume XVIII. New York, U. S. A., Thursday, July 16, 1908. No. 16

STUDEBAKER PLANS BUGGY TYPE

High Wheel Motor Vehicles to be Built for Farmers' Trade—Chassis Order Has Been Placed.

Having become convinced of the growing demand for the buggyabout type of automobile, the Studebaker interests of South Bend, Ind., have set in motion a part of their vast selling machinery to arrange for the marketing of a new production along this line, which is shortly to make its appearance. Arrangements for the manufacture of the vehicles have but recently been completed, but already an order for a large number of the chassis has been placed with the Speed Changing Pulley, of Indianapolis, Ind.

While the order that has already been placed is in a sense only a preliminary, its size may be appreciated when it is known that it was a factor in influencing the removal of the Speed Changing Pulley Co. to Anderson, Ind., this fall, from which town it received ten acres of ground and $75,000 for the erection of a new plant.

That so prominent a concern as the big wagon makers should join the ranks of the builders of the high wheel machine is significant of the growing popularity of this type of vehicle, and is therefore of considerable interest to the trade. The venture into the buggyabout field was only taken after a careful sounding of the market through the agencies of an enormous vehicle business closely in touch with the agricultural communities.

Woods Will Make "Woodsmobiles."

Walter A. Woods has resigned his position as treasurer and general manager of the Cleveland Motor Car Co., to head a new concern with a capitalization of $300,000 and which will be known as the Walter A. Woods Manufacturing Co. Its product will be a car called the "Woodsmobile," which will be made in Milwaukee. The chassis will in many respects resemble the 1908 Cleveland, for which Woods was largely responsible. It will have the Continental motor, four cylinders, 5 by 5 inches, selective transmission with four speeds forward and reverse, an improved multiple disc clutch and a number of detail refinements. The price complete with top, glass front, lamps, and full equipment, has been set at $3,500.

A six story building on "automobile row" in New York City has been engaged for salesroom, garage, stock room and repair shop, which it is expected will be opened about the first of September. Meanwhile the temporary offices are in the Miller building, 1931 Broadway, New York City.

Building Plant at Anderson.

The Speed Changing Pulley Co. has broken ground on a ten acre plot at Anderson, Ind., for a new factory which is to be of iron and brick construction. Work has been started on three large buildings and others will be added as occasion requires. The machine shop, half of which will be two stories high, will be 550 feet long, while the building which will contain the power plant for the foundry and blacksmith shop, and the carburetter manufacturing department, will be 310 feet long and 40 feet wide. The third building will be an office and store room. President E. S. De Tamble says that the new plant will be ready for occupancy about the first of September.

Sheriff Seizes Earl Motor Car.

Seizure by the sheriff of all the visible assets of the Earl Motor Car Co., of Kenosha, Wis., which is said to have made about 100 cars this year, has temporarily put a halt on its activities. The action was taken on a $90 claim filed by the Automatic Screw Co., of Cincinnati, O. The company was promoted by Charles Rohde, of Milwaukee, and a reorganization is now being planned, with capital from Escanaba, Mich., to assist. Thomas H. Booth, of Chicago, who has been actively engaged in the management, has retired but will retain his stock.

HARRIMAN A MOTOR CAR MAKER

Backs Million Dollar Company to Build Gasolene Railway Cars—Utilizes Union Pacific Experience.

E. H. Harriman has launched into the field of "automobile" railway cars and is backing a million dollar company in Omaha to manufacture gasolene cars for railroad and other use. The new company, organized under New Jersey laws, which is to be known as the McKeen Motor Car Co., is built up on the work done experimentally by the Union Pacific Railroad in devising gasolene suburban cars for its lines. W. R. McKeen was the superintendent of motive power and machinery at the time the experiments were undertaken and it is he who will head the separate enterprise as president and general manager, having resigned his place with the Union Pacific. All the patents under which the company will operate and which McKeen took out while employed by the Union Pacific, have been assigned to E. H. Harriman, who will look after the financial end.

Acting under instructions from Harriman, president of the Union Pacific Railroad Co., McKeen two years ago began to experiment with gasolene motors to propel passenger cars. The first car had a 50 horsepower motor and it was soon seen more power was needed. No. 1, with its light engine is still doing business and every car which has been built by the Union Pacific has been a revenue producer. Car No. 2 was then built with a 100 horsepower motor and it did good service, but the cars were crowded so heavily and a trailer was needed for baggage and express that it was decided advisable to put in a 200 horsepower engine. That is the size now in use and being installed in the new cars which are being built. These cars have been sent to all parts of the United States. Their greatest value lies in the small fuel charge and they can be operated with fewer men than a reg-

Digitized by Google

ular train, while doing the work of the latter as satisfactorily as steam.

Motor cars are not the only products which will be turned out by the company. A gasolene locomotive for switching purposes around private plants, will also be built. Railroads may no longer switch cars around a private manufacturing plant free of charge, and the plant cannot afford to pay the switching charge. To fill the want, a gasolene locomotive will be built, which will be able to handle cars around a plant.

"The company will build gasolene motor cars for the commercial world at large and we will begin building additional cars at once at Omaha," said McKeen, when asked where the new motor car shops were to be located. "We have now at the Omaha shops 41 cars completed or under construction and the first business of the new company will be to complete the cars now partially built. The arrangements for the enlargement of the shops to provide facilities for the future construction of these cars on a large scale are not crystalized, but at present the cars will be built in Omaha.

"The demand for these motor cars is large and could not be met when the shops were operated as a part of the Union Pacific shops. We cannot confine the usage of this wonderfully economical means of transportation to one road, and consequently a separate corporation has been formed to manufacture these cars upon a large scale."

Diamond Lands a Big Marsh Rim Order.

One of the first large contracts for 1909 accessories has been written by the Diamon Rubber Co., of Akron, O., for the equipment of 2,500 Chalmers-Detroit cars with Marsh quick-acting rims. According to the Diamond Rubber Co. this is the largest single order for quick acting rims ever given. The sale of the rims has doubled in 1908 over 1907, and indications point to a further large increase for the coming 1909 season.

Garwood Gets a Motor Plant.

Garwood, N. J., is to have a motor manufacturing concern in the Hicks Manufacturing Company, which begins operations this week. Albert B. Craft, of Cranford, N. J., is the agent for the concern, and associated with him are Henry E. Hicks, of Plainfield, and William B. Elliott, of Westfield.

Coil Makers Expand Their Factory.

The Jacobson-Brandow Co., of Pittsfield, Mass., which recently entered the field of spark coil and accessory manufacture, is extending its factory facilities. New quarters have been taken in the Gamewell block on Columbus avenue.

Haynes Has Settled on One Model.

Only one model will be made by the Haynes Automobile Co., of Kokomo, Ind., for the 1909 season. The concentration will be effected on a car which will sell at $3,000.

The Week's Incorporations.

Little Rock, Ark.—Little Rock Auto Co.; capital stock increased from $10,000 to $20,000.

New York City, N. Y.—New York Coach and Auto Lamp Co.; capital stock increased from $5,000 to $20,000.

Orange, Conn.—West Haven Motor Co.; certificate of dissolution filed by F. A. Watrous and E. T. Hazlehurst.

Spencerville, O.—Spencerville-Lima Auto Transit Co., under Ohio laws, with $10,000 capital. Corporators—A. D. Adkins and others.

Salt Lake City, Utah—Knight Carriage and Automobile Co., under Utah laws, with $50,000 capital. Corporators—John A. Knight, John M. Knight, William A. Knight.

Chicago, Ill.—Universal Automobile Appliance Co., under Illinois laws, with $20,000 capital; to manufacture and deal in automomobiles and appliances. Corporators—C. Anred, R. P. Bates, William H. Enrich.

Moline, Ill.—Velie Motor Vehicle Co., under Illinois laws, with $10,000 capital; to manufactur and deal in motor vehicles, gasolene, electric or steam. Corporators—Willard L. Velie, Otis E. Mauser, Stuart Harper.

Jersey City, N. J.—Safety Electric Operating Co., under New Jersey laws, with $500,000 capital; to manufacture, operate, buy and sell motor vehicles. Corporators—H. W. Andrews, G. E. Osborne, Charles D. Montague.

Chicago, Ill.—Bell Speedometer Co., under Illinois laws, with $50,000 capital; to manufacture speedometers and other automobile and bicycle supplies. Corporators—Dwight B. Carmichael, John F. Power, James S. McInerney.

Jersey City, N. J.—National Taxameter Co., under New Jersey laws, with $30.000 capital; to manufacture, buy, sell or deal in any article, product or accessory thereto used in transporting either persons or property Corporators—Ernest P. Burritt, F. E. Ellison, Albert White.

Grabowsky Joins Independents.

Another member has been added to the American Motor Car Manufacturers' Association in the Grabowsky Power Wagon Co., of Detroit, Mich. The general manager and designer is Max Grobowsky, who was for several years connected with the Rapid Motor Vehicle Co., of Pontiac, Mich., of which his brother, Morris Grabowsky, is secretary. The new company is making a specialty of sight-seing cars, police patrols, and commercial wagons, a removable power plant being a construction feature. It will exhibit at the Grand Central Palace show.

Will Make "Ruth" Automobiles.

In the footsteps of the famous foreign designer, who names his cars after his daughters, Milo Daniels, of North Webster, Mass., is about to produce the "Ruth" automobile. With his father, Charles Daniels, he has formed a company and secured a factory, where operations have commenced.

Sanders a Franklin Field Man.

F. H. Sanders, for several years a Franklin demonstrator and salesman for Adams & Hart, of Grand Rapids, Mich., has been engaged as a field salesman for the H. H. Franklin Manufacturing Co., of Syracuse, N. Y. He leaves in the near future for an extensive trip in the northwestern territory, visiting dealers and instructing them as to the mechanical features and selling points of the latest Franklin models.

Selden Testifies in Ford Suit.

Testimony in the famous suit against the Ford Motor Co. and others as to the validity of the Selden patent is being given this week by George B. Selden himself in the sur-rebuttal proceedings. It will be four years next October since the litigation commenced in earnest and the mass of testimony taken in that time would, in its printed form, fill a small library.

Velie Vehicles for Moline.

Moline, Ill., is to have another automobile manufacturing concern in the Velie Motor Vehicle Co., which has been incorporated with a capital stock of $100,000. The new company is an offshoot of the Velie Carriage Co., of Moline, its incorporators being W. L. Velie, Otis E. Mansur, and Stuart Harper, all of whom are directors in the older company.

Aldrich to Sell Aluminum.

Raymond D. Aldrich, well known to the trade as a lamp salesman and former representative in Detroit for the Brandenburg Brothers Co., has gone with the U. S. Bronze Co., of Cleveland, Ohio. He will push the sales of the complete line of aluminum specialties which the company makes for the automobile industry.

Loos Starts in for Himself.

W. L. Loos, former manager and purchasing agent for J. T. Bill & Co., at Los Angeles, Cal., has gone into business for himself in Oakland. Automobile accessories and supplies will constitute one of his jobbing lines, and complete machines will be handled also at his retail store.

Hatch Resigns from Thomas.

Mason B. Hatch has resigned his position as sales manager of the E. R. Thomas Motor Co., of Buffalo, N. Y., to go into the retail field. He will handle the Chalmers-Detroit line exclusively in Buffalo and surrounding territory.

Open Permanent Headquarters.

The Philadelphia Automobile Trade Association has opened a permanent headquarters for the convenience of its members. Rooms have been taken at Suite 216 in the Odd Fellows Temple.

POPE RECEIVER'S JUNE REPORT

Statement for the Month Under the Connecticut Receivership—The Figures Given in Detail.

The June report for the receivers of the Pope Mfg. Co., in Connecticut has been filed with the clerk of the Superior Court in Hartford. The cash balances in the banks and in the office total $587,338.47, with some $109,000 outstanding, while the accrued liabilities of the receivers have amounted to $48,117.47.

The detailed statement follows:

Balance in banks and cash in office, May 31, 1908		$422,261.64
Cash Receipts for June, 1908.		
Receipts from collection of accounts and notes receivable of Pope Mfg. Co.:—		
Hartford accounts		$831.18
Westfield accounts		445.58
Hagerstown accounts		2,220.37
		$3,497.13
Receipts from sales by receivers.		$254,163.49
Receipts from deposits by customers on orders for automobiles		3,985.00
Interest Received:—		
On notes receivable	$1.00	
On bank balances	2,258.00	
		$2,259.00
Rental from Thompsonville factory		100.00
Refund of special advances		7.14
Returned insurance premiums		7.76
Misc. items of income		23.00
Receipts from and for account of receivers:—		
In Massachusetts	$1,148.95	
In Maryland	180.88	
In Illinois	1,050.00	
Pope Motor Car Co., Toledo	3.93	
Pope Motor Car Co., Indianapolis	81.33	
Federal Man. Co.	8.15	
	$2,473.24	$266,515.76
		$688.777.40
Cash Disbursements for June, 1908.		
Refund of deposits received on misc. undelivered orders		$3,672.62
Receivers' expenses and payments for purchases:—		
Payrolls factory and office		$44,650.45
Misc. and selling expenses		794.95
Material and supplies		47,480.80
		$92,926.20
Receivers' fees:—		
Albert L. Pope		$500.00
George A. Yule		500.00
		$1.000.00
Payments in settlement of accounts with:—		
Receivers in Mass.	$933.47	
Rec. in Maryland	2,530.44	
Rec. in New Jersey	263.77	
Rec.in Toledo	56.84	
Rec. in Indianapolis	55.09	
	$3,840.11	$101,438.93
Balance in Am. Nat. Bank	$325,263.84	
Balance in Phoenix Nat. Bank	260,126.52	
Balance in First Nat. Bank	266.19	
Cash in office	1,681.92	
		$587,338.47
Accrued Liabilities of Receivers:		
For materials, supplies and miscellaneous expenses		$45,846.69
For payrolls, factory and office.		2,270.78
		$48,117.47
Balances due receivers of Pope Mfg. Co. and Pope Motor Car Co., from other districts		624.57
Accounts receivable from sales of receivers May 31, 1908, per last report		181,997.15
Sales of receivers for June, 1908.		201,700.55
		$383,697.70
Less cash collections for June, 1908	$254,163.49	
Deposits credited to accounts receivable, cash discounts and miscellaneous contra accounts	30,246.05	$284,409.54
		$99,288.16
Balances due from receivers of Pope Mfg. Co. in other districts of receivers of Pope Motor Car Co. for transfer of merchandise and supplies, and advances for expenses		$9,801.02

Selden's Patent Share is Sure.

Out of the $46,173.29 disbursed by the receivers of the Electric Vehicle Co., of Hartford, Conn., during the month of June, not the least interesting item is the sum paid George B. Selden for his share of Selden patent royalties and amounting to $11,-745.45. The cash receipts for the month were $47,265.82.

The cash statement of receipts and disbursements is as follows:

Receipts.	
Cash on hand June 1, 1908	$120,104.11
Cash collected on E. V. Co. acct.	515.85
Cash collected on receivers' account	46,120.37
Cash interest Am. Nat. Bank	629.60
	$167,369.93
Disbursements.	
Payroll	$17,884.00
Traveling expenses	315.70
Purchasing creditors	12,853.98
Freight and express	80.24
Commissions	250.00
Petty cash	484.78
Telegraph and telephone	17.19
Legal expenses	1,591.95
Receivers' salaries	800.00
Storage	150.00
G. B. Selden	11,745.45
Cash receipts	$167,369.93
Cash disbursed	46,173.29
Balance on hand July 1, 1908.	$121,196.64

Lindsley to Enlarge.

An extensive enlargement of the Lake & Neff automobile works at Dowagiac, Mich., is in prospect under the new ownership of the J. W. Lindsley Co., of Chicago. Frank Lane has been retained as manager of the plant.

TRADE SOUND IN WESTERN STATES

DeLisser Saw Strange Contrasts in Automobile Demand—Ajax Changes Follow His Trip—Agents Entertained.

Just returned from the Pacific Coast, with fresh impressions and some unusual observations on business conditions, Horace De Lisser, president of the Ajax-Grieb Rubber Co., of Trenton, N. J., takes a very healthy and satisfactory view of the outlook, seasoned with some little surprises in what he saw. His trip took in everything from Seattle to Los Angeles and all the principal places en route.

In San Francisco general business is still dormant, he found, the banks preferring to lend money on building operations, which are very extensive. In the automobile business a peculiar state of affairs exists in that light touring cars are much in demand, while runabouts appear to be a positive drug on the market. In Los Angeles he found exactly the reverse to be true, with no explanation observable.

With the exception of the flooded district in Kansas, bumper crops are general in the agricultural sections, with a corresponding local prosperity in every instance. As the farmer is assured of plenty of money, De Lisser looks to the West as a big market for the medium and low priced machines. Evidences that many manufacturers are laying extensive plans for this business also came within his notice.

The tire business he found in very good condition, and to aid its development so far as Ajax tires are concerned, he left a number of changes in his wake, which are to take effect almost immediately. Among these is the bringing to New York of Harold Stimson, manager of the Seattle branch, who will become assistant to the president at the New York office, having immediate charge of the branch houses, of which there will shortly be ten. Frank Lumsden, formerly of the Ford Motor Company, succeeds Stimson as manager at Seattle. George Packer, formerly of the Scott Tool & Supply Co., has been appointed manager of the Denver branch. A new branch in Kansas City will shortly be established on Grand avenue, and this will be in charge of a prominent tradesman of that city with whom negotiations have been practically closed. Still another branch will be opened in Philadelphia, the exact location of which has not yet been decided upon.

Hardly had De Lisser arrived in New York before he came upon the convention of branch managers of the Maxwell-Briscoe Motor Co., 23 in number, in session at Tarrytown. These he corralled for a trip in a special Pullman to the new Ajax-Grieb factory on Tuesday, where they saw Ajax tires in all stages of tire making, returning to New York for dinner and the theater.

FRANKLIN Automobiles

Is "something for nothing" any more likely in automobiles than elsewhere?

Look at what Franklins do; and the little they cost to do it. Look at how they are made. Ride all day in any Franklin. You enjoy every minute. So do your passengers.

You get all the speed you want. You do things on hills that no other automobile of the rating can touch. You keep on going—never mind grades, sand, mud or the rocky, bumpy stretches that knock the life out of a stiff steel-frame automobile with half-elliptic springs.

This sort of going in such an automobile wastes the engine power, wears out the machinery rapidly and is hard on the passengers.

The Franklin with its large wheels and tires, its four full-elliptic springs and its laminated wood-frame doesn't mind these jolts and jars. They don't reach the engine nor the passengers.

You leave the hard-riding automobile behind. You do it with perfect comfort and less wear and tear and less operating cost.

Franklins weigh on an average a third less than other automobiles of similar capacity; so that you carry the same passengers for a third less tires and a third less gasoline.

Even at the same weight the air-cooled Franklin engine does the work on 25 per cent. less fuel than a water-cooled automobile. And you have no plumbing system to fuss with—no water to leak nor boil, nor to freeze in winter. You can use your Franklin any minute day or night every day in the year.

You can't wear out a Franklin. The first experimental Franklin made in 1901 is in good use to-day. So are all we ever made, so far as we know.

Franklins are not cheap to make. Their materials and construction are the highest grade. They cost a good deal more *per round* than ordinary automobiles. But considering the work they do and their low-running cost and their 365 days of service in a year, and the long time they last, they are after all the most economical automobiles you can buy.

You get what you pay for. Franklins are worth the money.

The Farmer as an Automobile Buyer.

That conception of manufacturing which believes in finding out what can be sold and where it can be sold, and then making it to be sold there, rather than to confine production to some arbitrary fixed ideal, has certain opportunities in automobile manufacture at the present time which are not to be overlooked. These arise from the fact that this year no small portion of the money of the country seems likely to lie for quite a period to the credit and at the disposition of that portion of the populace which has devoted itself to the coaxing of products from the ground and which this spring has been rewarded with promises of extremely abundant and fruitful returns. This alone would not be sufficient were it not that coupled with the affluence now in prospect there is an itching for motor car possession and a conviction that the automobile has practical benefits from a business and economical standpoint.

To strip the proposition of all its euphemism, that neglected and in some quarters despised customer, the farmer, is going to spend money for automobiles this season to an extent that is unbelievable to those who have not given the matter study. The business that has already been done in motor vehicles designed with particular regard to his purse and fancy has reached astonishing proportions, its volume being such as to attract the commercial sense of at least two of the largest organizations that have relations with him.

Those who insist on doing business with the kid-glove and check-book set or not at all, may see no possibilities in the well recognized prosperity of the agricultural communities. To them the thoughts of dealing with so rude and uncouth a class, which bears traces of stinginess, are more or less impossible, due to certain antiquated impressions and prejudices which actual contact with the Western farmer would quickly remove. But for the manufacturers who can adapt themselves to conditions and markets, without sacrificing any tenets of sound business, the assured prosperity of the Western farmer is a call to action.

Future of the Electric Vehicle.

That the field for electric vehicles never as yet has been exploited to anything like its full value, is a conclusion which must develop on close consideration of several of its peculiar characteristics. Up to the present, it has been more or less in competition with other power driven vehicles intended solely for highway service. Yet even in that respect it has become differentiated, in that its fitness for metropolitan service, as contrasted with that over the common dirt highway, and for commercial as contrasted with purely pleasure duty, have become its leading features. In one or two of its commercial applications, which have only recently come to notice, though by no means of recent origin, however, lie the germ of what may be considered one of the brightest sections of its future field.

The experimental use of electric trucks by the Pennsylvania Railroad for freight and baggage transfer, opens an extensive outlook in itself, but not half as suggestive as the kindred possibility of utilizing similar vehicles, of both large and small capacity for purposes of freight transfer in industrial plants. Take for instance the lighter type at present employed in railroad service, which, though strictly motor driven, is controlled like an ordinary hand truck, through a tongue which is held by the operator. With the great latitude of design which lies at the command of the electric vehicle designer, it would be perfectly possible to modify such a design in a number of ways to meet the demands of the necessary transportation which is now performed in large manufacturing plants by the aid of overhead cranes, telpherage, and more frequently, by means of ordinary push trucks.

Such vehicles, might be made with low platforms, the motor and battery being carried at one end, as in mine locomotives, and of capacities suited to the needs of the materials to be handled. Without limitation as to radius of travel, they might be shifted about from point to point in the plant, as occasion demanded, and employed either for long or short hauls. Similarly, larger sizes, following the more conventional design of the ordinary electric might be made to supplant even the industrial railway, and with economy, since no trackage, and no stationary plant other than the regular power plant, would be required. Their attendance need be only that of the driver, who also attends to the loading, while the batteries, charged at night, and massed under the care of a single electrician, would form in many instances, a welcome "equalizer" on the otherwise, low, night load of the power department. Among other advantages the simplicity of operation, low maintenance cost, low operating cost, and absence of noise and fire risk, which are reckoned in favor of the electric for road service, must count equally in its favor when given special applications such as these.

The real point of superlative excellence, which makes the suggestion of such uses tenable, is that the electric vehicle is absolutely flexible as to the nature and arrangement of its three elementary groups. There must be a running gear, a battery and a motor. These elements may be arranged absolutely at the will of the designer, subject to the peculiar demands of the service contemplated. Such advantageous qualities are lacking in self-propelled vehicles employing other sources of power, and their applicability to such purposes, really extraneous to the proper province of the automobile as ordinarily recognized, are limited accordingly.

The absolute tractibility of the electric current as applied in isolated power units, has given rise to a host of modern improvements in industrial undertakings, never dreamed of before the days of the portable

Digitized by Google

machine tool and to economies unheard of before the application of individual drives for machinery of various sorts. In a similar way, the development of the electric vehicle, especially of the small type adapted to special uses, gives promise of still other conveniences and economies, which even yet are unknown.

Friendliness of the Carriage Makers.

By contrast with its former hostile attitude, the present eagerness of the carriage-making industry and trade to cement itself more closely to the automobile business is, to say the least, interesting to behold. The production of bodies, which was the perfectly natural entering wedge, has been followed with a more cordial regard, until, after several years of constantly increasing business from this source, the carriage-makers in general have come to recognize an extremely profitable outlook in the repairing of motor cars. Now it has come to be appreciated that in performing the double function of carriage and automobile repairer, a full measure of business may be obtained, and dull times tided over—the more so, because, as a well, known journal of the trade puts it, "the average automobile is in the repair shop much oftener than the average carriage, on account of the useage and recklessness to which it is subjected."

"Were it not for the popularity of the motor car," as this authority continues, "many carriage shops throughout the country would be finding it difficult to weather the slack period in regular carriage work. Herein lies the advantage to carriage builders of catering to both branches of the trade. The carriage builder who can do a good job of automobile repairing is the man who is keeping the wheels of his business going these days."

And herein also, lies a certain disadvantage to the user, unless he be exceptionally fortunate in securing the services of a good machinist as well as a good carriage maker. For the automobile is still much less a carriage than a machine, and no store of knowledge relating to matters of carriage work alone, is sufficient to cope with the demands of the hybrid modern mechanism of the elaborate car. As has been pointed out more than once, the province of the carriage builder is essentially confined to the production of bodies. The mechanical side of the motor car, he may work up to, as it were, but his early experience and the traditions of his trade are in many respects at variance with its best practices. Therefore, it behooves the user and the manufacturer to be cautious in entrusting work of the mechanical sort to carriage builders, unless they are especially equipped to handle it. Ultimately, the importance of their position is destined to be of the greatest significance. But the alliance must be a gradual one and conservatively advanced on both sides.

Needs of the Country Garage.

To the automobile tourist is given an opportunity of contrasting broadly the garage conditions afforded by the typical metropolitan establishment, and the average country equivalent which stands as substitute for it by necessity, though seldom from choice. The differences are mainly due to the relative natures of the "plants," in the two instances, and they, in turn, to the differences in the amounts of business carried and the outlay warranted thereby. But in the last analysis, it is evident that the average country garageman, like many of his brethren in the town, is wasting his efforts merely through lack of ability to foresee what his patrons will be apt to require, and lack of tact in caring for their needs.

Some one has defined a garage—as though a definition were of any particular use—as serving a three-fold purpose, namely that of a store for the supply of fuel, lubricant and other running necessities; a machine shop, where repairs of any and all sorts may be performed; and a repository for the safe keeping of the machines during the intervals between their periods of service. The distinguishment thus afforded between the various divisions of the main purpose of the garage is useful in this connection because too many garagemen lose sight of the fact that these purposes are distinct.

What the average city garage has, which the average country garage has not, is above all, system and departmentization. It is true, that in the small plant, it is difficult to separate the various divisions of the work, and that confusion and its kindred difficulties follow very often merely through lack of space, and lack of funds to establish a systematic arrangement. But when the proprietor has a clear idea of the advantages of cleanliness and order, he is usually able to do a great deal toward remedying even this defect in his surroundings.

System is, to a degree, self-propulsive. If a certain article has a stated place, its absence from that place indicates neglect, and conversely, its very presence in good condition, suggests its use. Once a garage, no matter how limited its scope, has been placed on an orderly basis, and organized along right lines, it becomes attractive to the user, and, as is particularly true with the country garage, the transient customer may become either a friend of a foe, according to the treatment accorded him.

The garage business resembles in many of its aspects the hotel business. Once the proprietor has learned the secret of so pleasing his patrons as to enlist them in his service, the relative value of his geographical location becomes of measurably less importance. The principle applies in degree to the garage. The sophisticated metropolitan garageman has learned the secret of pleasing his patrons by a dozen little attentions which his experience has taught are of value. The man with a small place outside the city limits, is too prone to regard his location as an unprofitable one from the standpoint of large volumes of business, and to overlook the importance of those little details which count for so much in the long run.

COMING EVENTS

Sept. 1, 2, 3, and 4, Chicago, Ill.—Chicago Motor Club's postponed 1,000-mile reliability run.

November 26, Savannah, Ga.—Automobile Club of America's (New York), 400 miles outlaw race for foreign cars.

December 31-January 7, New York City—American Motor Car Manufacturers' Association's annual show in Grand Central Palace.

January 16-23, New York City—Association of Licensed Automobile Manufacturers' annual show in Madison Square Garden.

Statistics gathered directly from the user by the various makers, in many instances have formed valuable contributions to the fund of general information on the subject of the costs of motoring. The outcome of a recent prize competition for chauffeurs is the latest instance in point, furnishing as it does, an astonishing revelation of the possible maintenance cost of new, high powered and well made machines. It must be borne in mind, however, that these are exceptional figures rather averages in the absolute sense. They show what it is possible to accomplish where proper care and a good machine are brought together.

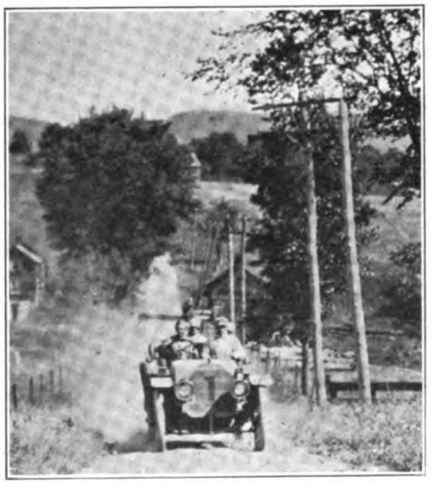
IN HOT PURSUIT OF GLIDDEN TROPHY

The standing of the teams in the Glidden competition was on Wednesday night, July 15, as follows: Automobile Club of Buffalo, Team No. 1, (Pierce Great Arrows, Nos. 1, 2 and 3), perfect score; Automobile Club of Buffalo, Team No. 2, (Reo, No. 4, and Premiers, Nos. 8 and 9) perfect score; Chicago Motor Club Team, No. 1 (Haynes, Nos. 19 and 20, and Olds, No. 35), perfect score; Rochester Automobile Club Team, No. 2 (Studebakers, Nos. 24, 25 and 26), perfect score; Bay State Automobile Club (Marmons, Nos. 21, 22 and 23), perfect score; Columbus Automobile Club (Peerless, Nos. 5, 6, and 7), perfect score; Chicago Motor Club Team, No. 2 (Rainier, No. 15, and Oakland, Nos. 27 and 28) 997⅔ points; Rochester Automobile Club Team, No. 1 (Selden, No. 32, Gaeth, No. 10, and Thimos, No. 11), 666⅔ points; Cleveland Automobile Club (Garfords, Nos. 29, 30 and 31), 664⅔ points; Automobile Club of Syracuse (Franklin, Nos. 12, 13 and 14), 626⅔ points. For certificates only, Stevens-Duryea, Nos. 16 and 17, perfect scores.



For the Hower trophy for runabouts the standing was as follows: Pierce Arrow, No. 100; Pierce Arrow, No. 103; Premier, No. 104; Stoddard-Dayton, No. 107; Stoddard-Dayton, No. 112, perfect scores.. Reo, No 101, points remaining, 988; Overland, No. 110, points left, 967; Stoddard-Dayton, No. 109, points left, 832; Franklin, No. 106, points left, 819. The cars out are Gearless, No. 105; Overland, Nos. 108, 110 and 111; Gyroscope, No. 113, and Moline, No. 102, the latter two continuing as non-contestants with the intention of making the entire distance of the tour.

STARTING THE TOURISTS FROM BUFFALO—TYPICAL CROWD OF SPECTATORS

Busy policemen had a lively time keeping the crowds back so that the touring contest for the Glidden and Hower trophies might have a favorable start from Buffalo, on Thursday, July 9th. Promptly at 10 o'clock, however, the tour began and one by one the 56 cars intending to go the distance were sent off, accompanied by a few misguided enthusiasts who trailed along for part of the first day's trip. The 46 competing cars had been parked in official open air garage space the night before, under the direction of the chairman of the tour, so that there was no delay in lining them up for the start.

The first day's run, from Buffalo to Cambridge Springs, Pa., a distance of 117 miles, gave a route which for a large part of the way skirted along the edge of Lake Erie. The schedule of 5 hours and 52 minutes for the big cars was very easy, as almost all of the drivers took advantage of the good roads to get in some fast work. John Breyfogle, driving a Gearless car in the Hower class, was the first to suffer mishap, his machine striking a telegraph pole near Westfield, N. Y., just 62 miles from Buffalo. A broken frame and other damages put the car out of the contest. L. A. Talbot, driving a Franklin, broke a spring, but by ingenious welding at a blacksmith shop was able to repair it himself, thus avoiding penalization. On arriving at Cambridge Springs it was found that there was much confusion as to the rules, particularly on the part of observers who undertook to instruct the drivers as to the interpretation. Minor errors of checking in were therefore overlooked, but a lecture and a warning were given in the evening by Chairman Hower.

GOOD GOING IN HILLY REGION

A change was deemed necessary in Friday's route for the run from Cambridge Springs to Pittsburg, increasing the distance from 110 to 127 miles. The time schedule for the big cars was accordingly increased from 6 hours and 30 minutes to 6 hours and 45 minutes. The roads were rough and rutty for half the distance, but very good the rest. The towns along the way gave a glad welcome to the tourists, and Newcastle, Pa., turned out en masse. The local cops held the crowds to the curb and waved the tourists to go through as fast as they liked. Those who accepted the invitation and gave speed demonstrations on the brick pavement were loudly cheered. A too zealous flagman, in clearing the road, walked directly in front of H. A. Van Tine's Garford car just as it was turning a corner at speed. Van Tine veered to the curb to avoid hitting him, and broke a wheel in skidding. He soon got a new wheel from a local agent, but was disqualified at Pittsburg because the extra wheel was not inventoried and carried along originally. This

MARSH RIMS

Chosen as Exclusive Equipment for a Total of 2,500 Chalmers-Detroit Cars

THE FIRST EXCLUSIVE RIM CONTRACT

ever written, it was given only after the most searching investigation and tests.

Quick acting in actual practice, not in name principally, Marsh Rims distanced every competitor.

100% EFFICIENCY

NO OTHER RIM CAN TOUCH THE MARK

"For ourselves, we insist on Marsh Rims. We recommend them everywhere," is the concensus of the leading trade's judgment.

Our 1909 proposition to manufacturers is vitally interesting—more, it is of extraordinary importance. We mean just this.

LOOK OVER THE ACCOMPANYING PAGE.

THE DIAMOND RUBBER COMPANY

FOR 1909 MARSH RIMS

100% EFFICIENCY

What Quick Acting Rim predominated in all the 1907-8 automobile shows?

THE MARSH—20 per cent. more of them on cars shown than the highest competing make.

What Quick Acting Rim has been mostly used in the Glidden and other tours and runs this year?

THE MARSH—Emphatically. Its superior record has been even more conspicuous.

What one Quick Acting Rim has been successfully used in racing this year and last?

THE MARSH AND THE MARSH ONLY—The winning of the 190-mile Savannah race is just a sample instance. MARSH RIMS stay on, but can be taken off and applied in a few seconds.

What rim has led all others in 1908 sales—not only to the trade but particularly upon consumer's specifications.

THE MARSH RIM—by a wide margin, and this without price juggling or private inducements.

In a word, it was THE MARSH RIM against the field for 1908, and THE MARSH RIM won.

For 1909 it is the same, and the field does not measure up to 100 per cent. efficiency—and never did and can't.

THE MARSH RIM has and does. Results talk. Absolute efficiency, unvarying reliability, ease of manipulation, safety and uniformity—against these there can be no offset.

THE DIAMOND RUBBER COMPANY

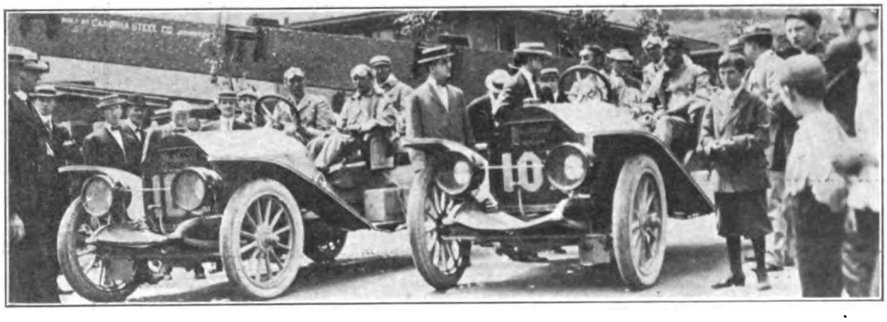
In Hot Pursuit of Glidden Trophy.

(Continued from page 523.)

brought 333⅓ points penalty against the Cleveland Automobile Club team. The Oakland No. 28, of the Chicago Motor Club Team No. 2, was penalized 7 points, bringing 2⅓ points against its club. A connecting rod bearing replacement was the cause. The Gyroscope car in the Hower class fell behind and did not get in until long after the others.

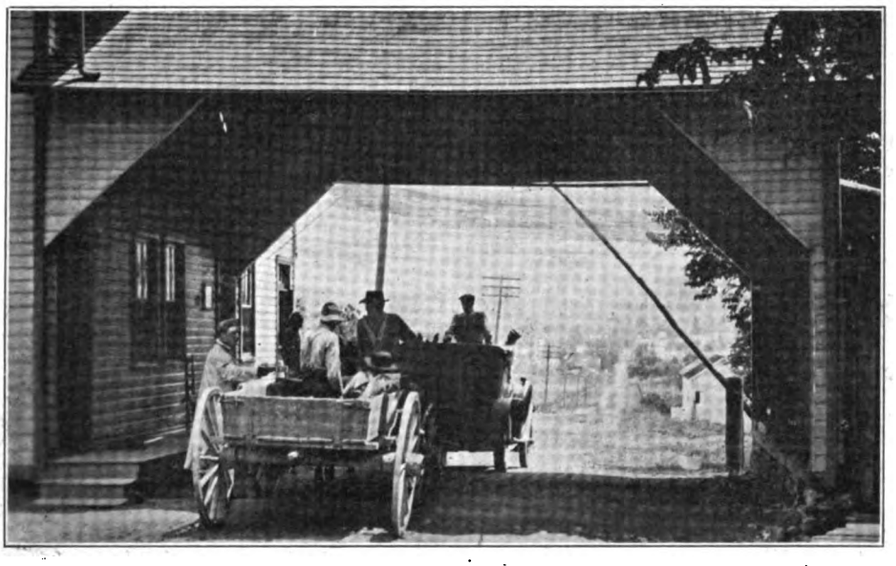


ONE OF THE MARMONS LEAVING BEDFORD SPRINGS HOTEL

Saturday's run, July 11, was 106 miles, from Pittsburg to Bedford Springs, Pa., with a seven-hour schedule for the biggest cars. Tortuous, winding roads, around the edges of cliffs took the tourists over one of the highest points in the Alleghenies, after which it was a dangerous slide, with smoking brakes, down to where Bedford Springs lies between the two main ridges of the mountains. The cars had to be driven to the limit that the roads would permit in order to make the schedule, and on alighting at the Springs the drivers and passengers could hardly walk for the bruising and jouncing that they had had. Their faces were covered with masks of hardened dust. To make their joy complete, they were given the cheering information that they had arrived just too late for lunch, although a few of the early ones were served. In the Glidden class, W. H. Hurlburt's Garford, No. 31, incurred 6 points penalty, bringing 2 points more against the Cleveland team. The Overland, No. 108, driven by Mrs. E. W. Shirley, lost 9 points from its Hower score through tardiness, the Hower trophy Stoddard-Dayton, No. 109, lost 168 points, and the Overland, No. 111, was disqualified with a broken spring. The Stoddard-Dayton's difficulties arose through a wandering spark from the magneto setting fire to the gasolene at the carburetter. A lively fire resulted, which burned several hands and coats that were used to put it out.

GREAT ARROW TEAM ENTERING HARRISBURG

STODDARD-DAYTON TEAM AT HARRISBURG



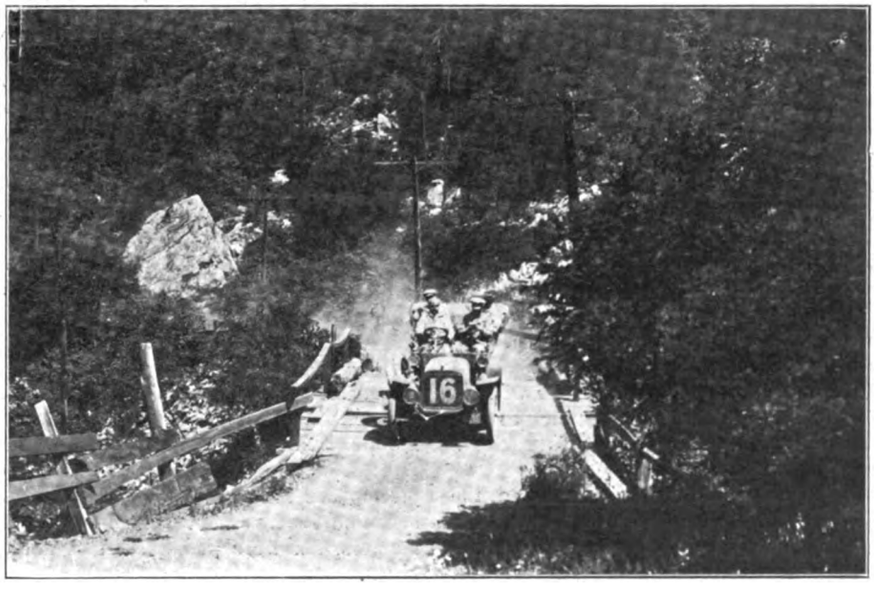
FRANKLIN TEAM—ONLY AIR COOLED CARS IN THE TOUR

Sunday at Bedford Springs was a day of rest, and everybody honored it as such by getting up late. The leisure of the day gave the tourists the opportunity to get acquainted. It was found that there were four women on the trip. Mrs. E. W. Shirley, Mrs. Joan Cuneo, Mrs. W. C. Marmon, who was with her husband, and Mrs. E. S. Berwick, with Mrs. Cuneo. An alleged Japanese prince was also discovered, Togia Ninagowa, supposed to be studying automobile matters in America and taking the tour for experience. But he did not prove half so interesting as Mrs. Cuneo's black mascot kitten, which was doomed to a violent automobile death the next day through too great a confidence in motor cars. The "Mudlarks," veterans of the endurance run to Pittsburg in 1903, got together and made merry, repeating the stories of that swim, but even their festivities did not last very late and everybody got to bed in good season.

The 13th was an unlucky day, not alone for the black kitten, which was killed. Two clubs were penalized and three Hower contestants lost points. It was 157 miles from Bedford Springs to Harrisburg, and the schedule was six hours. The Rochester Automobile Club, Team No. 1, lost 333⅓ points through the retirement of the Selden, No. 32, because of a broken spring, three miles from Harrisburg, while the Syracuse Club lost 20 points through a 60-point penalty

Digitized by Google

against Franklin, No. 12, which also had a broken spring. In the Hower class, Franklin, No. 106, dropped 181 points, the Moline, No. 102, lost 51 points, and Mrs. Shirley's Overland, No. 108, got 102 points more. On account of the sickness of her mechanic's father, she dropped out of the contest, to give the mechanician the chance to hasten home. It was a hard climb over



PAYING THE WAY AT SCRUB RIDGE, NEAR McCONNELLSBURG, PA.

the last half of the Alleghenies, enlivened by triumphal arches in some of the small towns, but down grade into Harrisburg was speedy and exciting. The Motor Club of Harrisburg did the honors at a smoker in the evening.

From Harrisburg to Philadelphia on Tuesday was an easy 134 miles, and no penalties were incurred except by the Moline, which limped in at midnight with cylinder trouble. "Rough Rider" Hurlburt drove his Garford in such romping style that he tossed Benny Smith, a mechanic, out of the car, and as empty air offered inadequate support, Benny fell with a thud on the road near Reading. He had been perched on the back of the car, with his feet on the rear seat, and was not prepared for the jolt that sent him out. However he absolved Hurlburt from all blame for his scratched face and bumped head. The Quaker City Motor Club gave a smoker at Horticultural Hall.

Wednesday, July 15, completed just six of the twelve days' touring, the run being from Philadelphia, through the Delaware Water Gap to Milford, Pa., which is in Pike county. The distance was 132 miles, and only Hower contestants suffered. Of these the Reo, No. 101, lost 12 points, and Overland, No. 110, dropped 33 points. The Moline, No. 102, withdrew to put in a new cylinder, and continue as a non-contestant.

The converse of "No news is good news," is almost equally true, that good news is no news, especially as applied to the cars in the tour, where accidents and penalizations constitute the chief topics of conversation and discussion. In the same sense it has been pointed out that there is no news in the fact that the cashier of the prominent bank did not abscond with the funds or that the great trust magnate still loves his wife, and the application follows in pointing out that in the Glidden and Hower contests a large number of the cars are running so regularly and surely as to be denied the attention that is their due.

RUSTIC BRIDGE, 50 MILES FROM PITTSBURG

There are six Pierce Great Arrows in the tour, three in competition for the Glidden trophy and representing one team of the Buffalo Automobile Club, two in the struggle for the Hower trophy, and one as an official car for the use of Charles J. Glidden and Chairman Hower. All of them are in the hands of "home-grown" Pierce drivers who know their cars better than most men know their wives.

Three Marmon cars uphold the Bay State Automobile Club's claims for the trophy with an ease and steadiness that is calculated to make the club well content with its chances, while three Studebakers give the Rochester Automobile Club every reason for confidence. The Columbus Automobile Club is represented by three Peerless cars, painted red, white and blue, respectively, all of which have made perfect scores. Were it not that they are only competing for certificates, the two Stevens-Duryeas, with perfect scores, would make an element of team strength for any club, being able to hold their own in every circumstance. The Automobile Club of Buffalo, in its No. 2 team has mixed company, consisting of two Premiers and a Reo, and the Chicago Motor Club also has a mixture of makers in its No. 1 team, consisting of an Olds and two Haynes. All of these cars have run to the tune of perfect scores.

In the Hower contest the work of the two Pierce Arrows, the No. 104 Premier, the No. 107 Stoddard-Dayton, and the No. 112, Stoddard-Dayton has been so regular and uneventful that their less fortunate companions have attracted most of the attention. Needless to say, however, as the contest narrows down, the survivors with perfect scores loom more into the limelight.

As the donor of the trophy, Charles J. Glidden, feels entitled to views on the tour, and these he expressed at Harrisburg by saying; "This annual tour has progressed far enough to warrant calling it the severest test to which the automobile has ever been put and I doubt if a single car completes the long tour in a perfect condition. During my driving of the automobile I have witnessed several important endurance contests in different parts of the world, but have seen none requiring such skill, care and judgment of drivers as the one now un-

Digitized by Google

der way. Rumors are afloat that the winner will be challenged to a contest by some foreign and domestic manufacturers under the rules of 1907. Any manufacturer whose car arrives at Saratoga with or without a perfect score will be in a position to challenge the world and win any kind of a contest under the rules of 1908, which requires the careful scrutiny of observers appointed by a competing manufacturer."

The perfect score cars on club teams that were penalized through the mishaps to one or two of the trio composing them are apt to endure a shade of unjust stigma where they should be regarded with equal honor to those on teams no members of which were penalized. As individual performances their work is exactly the same. Two Franklins of the Syracuse team, the only air cooled make to be represented, enjoy the

SCENE EXEMPLIFYING POPULAR INTEREST

VIEW OF THE OPEN AIR GARAGE

immunity from penalties that comes of perfect performance, and similarly the Thomas, the Oakland, the Rainier, the Gaeth and the Garford are individually in the forefront with perfect scores.

Such cars as have incurred penalties have not been stripped of honor as a result, because in many instances there was no mechanical fault of the car itself involved in the circumstances which caused the penalization. In making the choice between possible physical injury to another and a spoiled score, the penalizations bear witness to the readiness of the contestants to forget, when need be, that there is such a thing as a score to reckon on.

In spite of the natural tension on the nerves due to the competition features of the affair, there has been no lack of the display of the more social and lighter side of life. At Cambridge Springs there was a great rush for a swim in the river and bathing pool, the scene resembling the scramble of schoolboys just released from class making a race to the swimming hole. Because of the more or less negligee costume which many of the drivers affect during the summer months there were all sorts and conditions of tan on exhibition, and those who could show the most and the blackest tan excited the same envious regard that is accorded the boy in the school yard who can wiggle his ears the best.

As a relaxation from the physical ardors of the trip, "Rough Rider" Hurlburt spent several quiet hours figuring out how big an automobile it would make if all the cars in the Glidden tour were rolled into one. After revising his mathematics several times he announced to a breathless audience that such a car would be so big that it would use up 150 gallons of gasolene for the trip, together with 20 gallons of lubricating oil and $4,000 worth of tires. Furthermore, it would have to travel 100,000 miles. Its cost would be over $100,000, and the depreciation on the trip would amount to $30,000, involving a total expense of $60,000 to put the car through the run.

As is usually the case, many of the roadside spectators think that the tour is something on the order of the Grand Prix or the Vanderbilt cup race, and shout encouragement to the drivers accordingly. Some of the more officious and thorough "rooters" rush out and hold up their fingers to indicate just how many cars are ahead, and urge extra speed to overtake them. Many of the crowds that had gathered in the small towns to see the tourists go through look positively grieved when the cars proceed at a modest pace and are pleased only when mufflers are opened and a seemingly reckless dash is indulged in.

Fourteen Made Perfect Scores.

Fourteen drivers earned perfect scores in the reliability run promoted by the Automobile Dealers' Association of Southern California on July 3, 4, 5 and 6, by completing 350 miles of give and take road on schedule time. Of the original number of starters, six were penalized, two failing to finish.

The long run started from Los Angeles on Friday morning, 3d inst., and the first day's journey took the tourists to San Diego, where a stop over night was made. Sixteen cars survived the first leg of the run without penalization, but two fell down on the run from San Diego to Riverside on Saturday. The roads were in good condition except in several sandy spots, and better results were made than on the first day. After a rest in Riverside over Sunday the tourists continued up the coast through San Bernardino to Los Angeles. The perfect score winners were:

Miss Gladys Moore, Cadillac; Mrs. W. J. Burt, Tourist; F. A. Raney, Stoddard-Dayton; R. D. Rose, Elmore; Lee Motor Car Co., Cadillac; Guy West, Auburn; H. E. Gilley, Autocar; Lord Motor Car Co., Studebaker; J. H. Bennett, Tourist; W. N. Congdon, Tourist; Joseph Pike, Auburn; V. S. Beardsley, Tourist; Greer-Robins Co., Mitchell, and J. S. Conwell, Tourist.

Huthbert Wins Rocky Mountain Run.

Charles Huthbert, driving a Rambler roadster, was declared the winner of the Rocky Mountain roadibility test, which spread over three days of bumping on Colorado roads and trails on July 2, 3 and 4, the day's run being from Denver to Colorado Springs and return, to Fort Collins and return, and again to Colorado Springs and return.

When the contest ended on Saturday night, five cars were found to have perfect scores, but as an absolute winner of the trophy had to be evolved the technical committee got out its pads, pencils and magnifying glasses and went over the cars critically. The result of this examination made the Rambler driver by Huthbert the victor.

The contest was more than a reliability run, with certain controls to make on time. It was a sealed bonnet test as well and 3 of the 16 starters were eliminated the first day, and 5 on the second. Eight cars finished in Denver on the last day, with five apparently perfect scores among them, the finishers being:

Charles Huthbert, Rambler; Eugene Grady, Pierce Great Arrow; Roy Yockey, Corbin; J. W. Billow, Mitchell; O. G. Linder, Gaeth; Martin Fletcher, Reo; G. A. Clarke, Great Smith, and S. E. Norton, Buick.

Automobiles to Unite Ohio Towns.

Transit facilities between Lima, Lafayette and Ada, Ohio, are to be afforded by the men behind the Spencerville Auto Transit Co., who are forming a new company for that purpose. They have purchased one large automobile which is to go into commission at once, and it is planned to have an equipment to run at least four trips daily between the points named. Full service is promised within a month.

CLOSE CONTESTS AT ARROWHEAD

Daring Climbers Safely Negotiate Depot Lane's Crooked Steep—Electrics Administer a Surprise to Doubters.

Contrary to all expectations there were no casualties at the Depot Lane hill climbing contest, held near New York City, on Saturday last, 11th inst., by the Riverside Motor Club, whatever that may be. Depot Lane, sometimes known as Arrowhead Hill, because it is near the Arrowhead Inn at 177th street and Lafayette boulevard, is a tortuous narrow lane averaging .15 per cent. grade and containing three turns. It is about one-third of a mile in length.

Because of the dangerous course, and expected casualties which did not occur, the events were not as well filled as they might have been and the contest did not attract a great crowd of people. The fastest time of the day was made by Arthur Dennison, driving a 48 horsepower stock car, when he covered the twisting lane in 23⅗ seconds, in the free-for-all class.

There was one feature of the meet that is entitled to consideration and that is that the various events were more closely contested than has been the case with other hill climbs in a long time. In the event for gasolene cars selling for over $4,000, which was won by William Bourque, the times made by all the cars were between 24⅗ and 25⅗ seconds, inclusive. The same feature marked all the events.

Some of the wiseacres went wrong when they predicted that the electrics could not get up the hill for they climbed right up to the top without hesitation and made better time than was scored in one of the gasolene events.

One of the features of the meet was an event for taxicabs, the first ever held in America. It was won by M. Kelar, in a Keaton, with Dennison second. Kelar climbed the hill in 35⅗ seconds, and the slowest time made in the event was 41⅘, illustrating how close the events were contested.

One of the features that did not materialize was a race between a four-in-hand of horses and an automobile. The events were disposed of so rapidly that the timing apparatus was torn up before the horses arrived on the scene. The summary:

Gasolene Cars Selling for $850 or Less.

Frank Dunnell, Ford..... 0;32⅖
W. H. Ladd, Maxwell 1:01⅖
A. Comancho, Gyroscope 1:14⅖

Gasolene Cars Selling from $851 to and Including $1,250.

Frank Dunnell, Ford 0:30⅖
Tommy Forbes, Overland 0:38⅘

Gasolene Cars Selling from $1,251 to and Including $2,000.

Tommy Forbes, Overland 0:45⅗
Manville, Palmer & Singer 0:49⅘

Gasolene Cars Selling from $2,001 to and Including $3,000.

William Bourque, Knox 0:20⅘
F. L. Lescault, Palmer & Singer 0:26⅗
William Dunnell, Ford 0:30⅗

Gasolene Cars Selling from $3,000 to and Including $4,000.

William Bourque, Knox 0:24⅕
Stewart H. Elliot, American 0:25⅗

Gasolene Cars Selling for Over $4,000.

William Bourque, Knox 0:24¼
K. Swan, Stearns 0:25⅖
Stewart H. Eliot, American 0:25⅗
Mitchener, Lozier 0:25⅗

Taxicabs; to Carry Four Persons, Including Driver.

Little Rock's First Hill Climbing Contest.

Fourth of July in Little Rock, Ark., was celebrated by a hill climbing contest and a mile road race, the first automobile events ever held in that city. The feature of the meet was the driving of B. H. Bricker, American. He won the hill climb with 3 seconds to spare, and was well in the lead in the road race when an accident put him out of the running. The summaries:

One Mile Road Race.

1 E. P. Ladd, Buick 1:10
2 I. K. Miller, Buick 1:24
3 P. W. Stift, White 1:33
4 George Daniher, Buick 1:43
5 A. N. De Mers, Buick 1:44
6 R. M. Baker, Buick 1:53
7 H. Blakeslee, American 2:36

Hill Climb.

1 B. H. Bricker, American 1:03
2 R. M. Baker, Buick 1:06
3 E. P. Ladd, Buick 1:32
4 P. W. Stift, White 2:12
5 H. Blakeslee, Franklin 2:22
J. K. Miller, Buick 2:56

Huntsville Owners Form a Club.

With a membership of 26 the automobile owners of Huntsville, Ala., on July 2d, organized the Huntsville Automobile Club. The officers are: President, Dr. J. G. Burman; vice-presidents, Sterling P. Metcalfe and Mrs. Mary Turner Clanton; secretary, Mrs. R. E. Smith; treasurer, Mrs. R. T. Baugh; chaplain, Rev. Francis Tappey.

Oklahoma Organizes State Association.

The Oklahoma State Automobile Association formed "to prevent oppression of or discrimination against its members," and to secure uniform legislation, has taken out incorporation papers. Lieutenant-Governor G. W. Bellamy, of Oklahoma, is one of the incorporators. The others are E. E. Blake, F. H. Wright, R. S. Trulock, G. W. Compton, E. D. Humphrey, and H. Harms.

A. A. A. DECIDES TO STAND PAT

Important Action of Central Conference Committee—Unanimous Decision to Retain Vanderbilt Cup Rules.

A proposal to curry favor with foreign racing interests by so modifying the conditions governing the forthcoming Vanderbilt Cup contest as to fall in line with the Ostend rules, was rejected at a meeting of the Central Conference Committee, representing the American Automobile Association and the American manufacturing bodies, held in Buffalo, N. Y., Tuesday of this week, 14th inst. The action followed a suggestion made in Paris to the Committee on Foreign Affairs of the A. A. A., to the effect that the recent action of the foreign clubs in refusing to sanction the event, would be rescinded if the racing board would consent to hold it under the conditions already in vogue abroad. In thus determining to stand pat on its original plans, not only are the American makers who are preparing cars for the race relieved of considerable anxiety and a deal of needless expense which otherwise would be incurred, but the dignity of the governing body itself is considerably enhanced.

Among those present at the Buffalo conference, including representatives of the National Association of Automobile Manufacturers and the American Motor Car Manufacturers' Association, were president Thomas Henderson and General Manager S. A. Miles, of the former body; E. R. Thomas, Chairman Jefferson De Mont Thompson and A. R. Pardington, of the A. A. A. racing board. S. D. Waldon and H. D. Chapin also represented the manufacturers. The decision rendered was taken only after a lengthy discussion of the situation, and was unanimous.

It was the spirit of the meeting that any other action than that taken would be unfair to the American makers, since it would not leave them sufficient time to build cars to conform to the changed rules. Further, the idea of a possible change of method in making up the foreign rules for another year also was taken into account. The hope was expressed, however, that in the event of possible recognition of the validity of the position of the A. A. A. in the future, a uniform method of car rating might be agreed upon.

Meantime, it is again announced that an "international flavor" will be imparted to this year's Vanderbilt race by the presence of several foreign cars, no less than four of which already have been entered. The course has already been selected, and is 25 miles long. As has been announced, it will be partly on the newly completed section of the Long Island Motor Parkway, and partly on local, State and county highways.

CAREFUL CHAUFFEURS WIN CHECKS

Remarkable Records Made in Long Contest for Winton Prizes—Frank Schneider Takes First Prize of $1,000.

When, in August last, the Winton Motor Carriage Co. offered cash prizes to the ten drivers of their new "Six-Teen-Six" who should show the best running records at the end of a year's use, it was not supposed that anything like 65,688 miles could be accomplished at an upkeep expense of $15.12½. Yet this remarkable showing has been obtained by totalling the records of the winners of the $2,500; which was the incentive for economical driving.

The conditions of the contest required that the contesting chauffeurs should render monthly reports of their mileage and up-keep, the reports to be certified by their employers; final affidavits were to be made both by owners and chauffeurs. Four newspaper men consented to act as judges.

First prize, $1,000, was awarded to Frank Schneider, chauffeur for Milton Schnaier, of New York. Schneider drove 11,683 miles in seven months, averaging 1,669 miles per month, at an upkeep cost of $12. Schneider's expense was not incurred until after the car had been driven 8,000 miles, and as no other contestant achieved this mileage without expense the judges were unanimous in awarding first prize to him.

The second prize of $500 went to Arthur Donovan, chauffeur for J. Axebrod, of New York. Donovan drove 7.570 miles in 3½ months—a monthly average of 2,162.8 miles, with no upkeep expense. The third purse of $250 was won by Harry Toomey, chauffeur for Harry S. Pickands, Euclid, Ohio. A record of 6,632.9 miles in 10 months, with absolutely no expense was his record. Toomey's report showed an expense of $284.85, but as this expense was incurred by an accident happening while the car was in the hands of the wife of the car owner, the judges ruled that it was not chargeable against either the car or the chauffeur.

The standing of the ten successful competitors in the order of their awards, is given by the accompanying table. Contestants whose totals erceeded 3,000 miles were awarded gold watches suitably engraved.

The Winton company has announced that the $2,500 contest for chauffeurs will be repeated in 1909, under conditions to be announced later.

Prize	Driver	Total Mileage	No. of Months	Average Miles per Month	Total Upkeep Cost	Average Upkeep Cost per Month
$1,000	F. Schneider, New York City	11.683	7	1,669	$12.00	$1.714
500	A. J. Donovan, New York City	7,570	3.5	2,162.8	0.	.000
250	H. A. Toomey, Euclid, Ohio	6,633	10	663.3	0.	.000
150	C. L. Bonner, Brooklyn, N. Y	6,806	8	850.7	3.	.375
100	J. Boice, Atlantic City, N. J	6,183	7	883.3	.025	.003
100	A. R. Cowperthwaite, Newton Center, Mass.	6.114	4.5	1,358.5	0.	.000
100	J. Arnold, Chicago, Ill	5.535	6	922.5	0.	.000

100	E. C. Knapp, Buffalo, N. Y	4.594	5.5	835.3	.10	.018
	Totals	65.688	61	1,076.8	$15.125	$0.25

Where Automobiles Make a Horse Useful.

By using a horse to pull automobiles to and from the washing stand, and for moving them about the garage, the proprietor of the Zacharias garage in Asbury Park, N. J., estimates that he can save $800 a year in salaries alone. Zacharias has been using this method for transferring cars for about a month and finds that the horse does the moving in about one-third of the time required by the four or five men necessary to move a car. The horse moves the cars with little difficulty.

The plan for moving the cars is very simple. A large hook is attached to the front of the car in taking it to the washing stand. A man is at the wheel and when going to fast the brakes are applied to stop it at the right place. In returning a car to its section, the hook is attached to the rear of the machine and the speed with which it is drawn back enables the car to run to the side of the garage steered in by a man at the wheel.

Police Chief Resorts to Mild Measures.

Chief of Police Corson, of Swampscott, one of the fashionable summer resorts near Boston, Mass., has concluded that traps for automobile scorchers are useless, and he has decided upon a better plan of securing observance of the speed regulations. When an automobile is seen going at a speed that is thought to be greater than the law allows, its number will be taken. The automobile register will be consulted, and the next day the owner will receive a notice that reads:

"Mr. ——. Dear Sir: Your automobile was going at a high rate of speed on (date) on (street).

"This notice is sent you to request you to be more careful in this town in the future. If not, we shall be obliged to prosecute."

Of the 2,150,000 miles of highway in daily use by the greater number of the inhabitants of this country, nearly 2,000,000 miles are earth roads.

MITCHELL CLAN MAKES MERRY

Second Annual Jubilee of California Owners Bigger than the First One—Ladies Compete in Hill Climb.

The second annual jubilee of the "Mitchell family" as the owners of Mitchell cars in California are designated collectively, held on July 2, 3 and 4, was a bigger success than its inaugural last year. While the first annual jubilee of the whole doggone Mitchell family was a success, since that time the family has been much blessed and multiplied, so that this year's reunion was marked by as large an outpouring as would a reunion of all the Young and Smith tribes in Utah.

Nearly 100 cars went from San Francisco to San Jose on July 3, and this number was augmented at the rendezvous by the arrival of other big Mitchells and the little ones as well from other California cities. San Jose's doors were thrown open wide to admit them and when the annual hill climb on Alumn Rock hill on Friday, 3d inst., was called the family was still arriving.

The course for the hill climb was a mile in length and as there was no trade rivalry to contend with the event was one of pure sport. Thirty-two drivers tried for the prizes offered in seven events, a large number of them being women.

Mrs. J. W. Skinner, of Stockton, started the ball rolling when she won the 1908 touring car class by driving her car up the incline in 1:21. John R. Chase, of San Jose, was second. L. Brassey, of San Jose, took the next event, for touring cars made prior to 1908, by covering the distance in 1:19. F. E. Hebbard, Santa Maria, was second and E. P. Lion, San Jose, third.

Another woman carried off the prize in the 1908 roadster class, Miss Marion Walcott, of San Francisco, doing the stunt in 1:34⅗. W. H. Pomery, of San Jose, was second in 1:35 and W. W. Wilson, San Francisco, finished third. In the runabout class for cars made prior to 1908 Dr. C. E. Mitchell, San Francisco, won a signal victory in 1:43⅕. Dr. R. L. Rigdon was second and H. O. H. Shelly third.

The ladies class for cars of any model was captured by Miss Walcott and Mrs. C. J. Brodie, won in the ladies' touring car class. Miss Walcott's time was 1:34⅗ and Mrs. Brodie climbed the hill in 1;26⅗.

The program for the Fourth consisted of a run from San Jose to Del Monte, and over 300 cars took part. In the evening there was an elaborate banquet, fireworks and a dance. The only sporting feature at Del Monte was a 17 miles speed judging contesst. The time schedule was 1 hour 30 minutes, and two drivers—Hugo Miller and Fred Edwards—made absolutely perfect scores by coming in exactly on the dot of time.

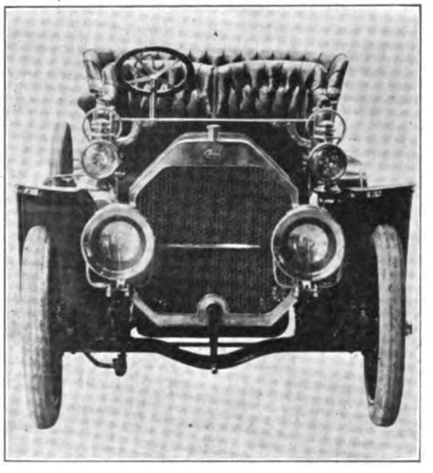
ORIGINALITY IN THE METEOR

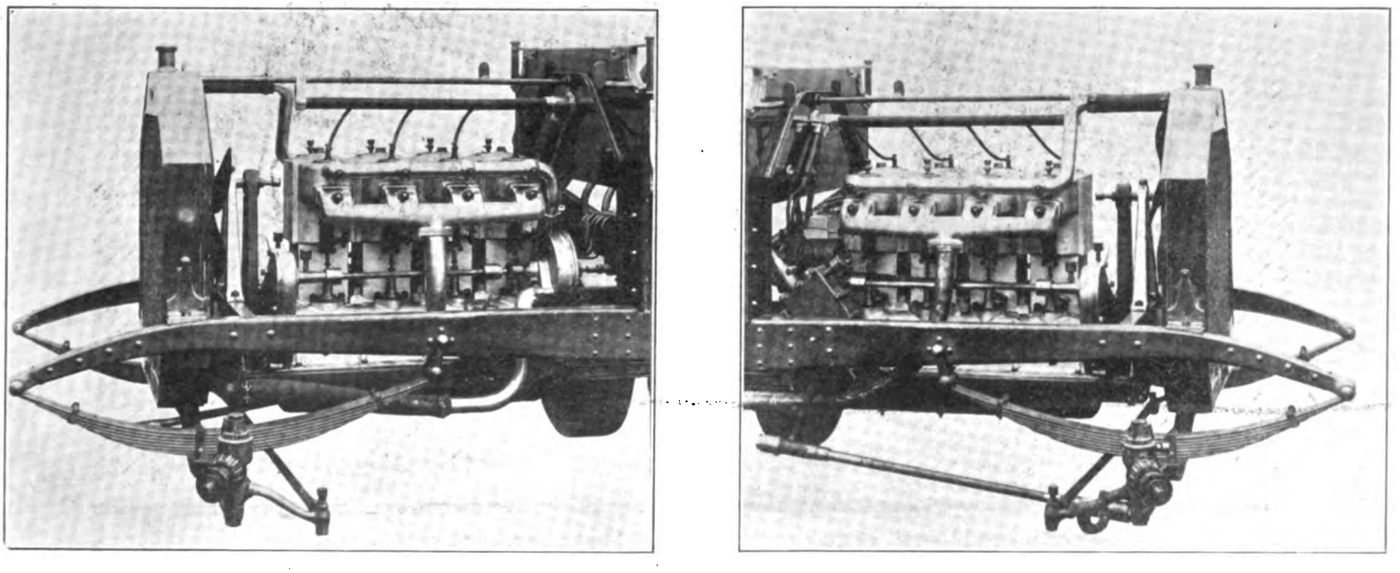
Special Features in Car That Relatively is a New Comer—Sturdy Type of Medium Powered Vehicle.



Among the cars which are to be reckoned with as relatively new comers in the field may be numbered the Meteor, which its makers, the Meteor Motor Car Co., Bettendorf, Iowa, have dubbed, "the car that does things." In earnest of the good intentions which lie back of the product, it should be added that though the car is practically a new comer, it represents no less than three years of work prior to its introduction. Of the machine in general, it is a sturdy representative of just over the medium powered class, selling at a figure just over what has come to be called the medium price. As the illustrations show, it possesses several original features, while conforming in general to standard specifications.

The motor, which is of the conventional four-cylinder vertical pattern, has cylinders of 5 by 5½-inch dimensions, valves disposed on opposite sides, and a special form of outer jacket wall permitting the use of large flat cover plates on either side, ensuring ample room for cleaning the castings and for inspecting the metal. The cylinders are cast individually from a special grade of hard, close-grained iron. The pistons are cast from the same material and are fitted with four packing rings, three at the top and one at the botom, in addition to which two oil-grooves are provided to assist in the distribution of the lubricant. The crank shaft is cut from the solid billet, is of specially heat treated, chrome nickel steel, and runs on five large bearings, ground to size. The cam shafts, which carry drop forged cams, keyed in place, are mounted within the crank case. The oiler and magneto gears as well as the pump transmission, run in oil. They are placed at the front end of the motor.

A commendable feature is the method of placing the magneto and lubricator, which are located at the back of the motor, as shown in the accompanying views, and directly under the foot board. They are therefore perfectly accessible at all times, and may be inspected without raising the hood, and merely by lifting the toe board.



METEOR CAR, SIDE VIEW

METEOR CAR, FRONT VIEW

Dual ignition is employed, the system including the Eisemann low tension magneto, batteries, and coils. All wiring is enclosed in black fiber tubes, running along the front side of the dash and over the cylinders, whence the separate connections are taken to the Eisemann magneto plugs, which are placed over the intake valves. The switch and compression release valve—the latter affording a relief of 60 per cent. of the compression—are the only devices mounted on the dashboard.

Transmission from the motor is through a special form of multiple disc clutch, enclosed in the fly wheel and running in oil. Provision for adjustment is made in the shape of four studs with lock nuts, which project from the rear side of the casing. The change gear group is of the selective

POWER PLANT OF THE METEOR CAR, SHOWING LOCATION OF MAGNETO AND LUBRICATOR

Digitized by Google

type, affording three forward speeds, besides the reverse, the third and highest giving a direct drive with all gears idle. The final transmission is through a propeller shaft, so designed as to work through a driving angle of about 2½ degrees, when the chassis is loaded to its normal capacity. The rear axle is of the floating type, of chrome nickel steel construction, and equipped with internal and external brakes, which are applied through balance beams.

The front axle is of I-beam section, mounted, like the other, on Timken roller bearings, even to the steering knuckles. The pressed steel frame is arched in the rear to afford the required clearance over the axle. Semi-elliptical spring mounting is employed in front. The members are 40 inches long. The rear mounting is of the platform type. The wheel base is 120 inches, and the wheels are 34 inches in diameter, shod with 4½ inch tires, front and rear. The total weight is 3,000 pounds.

The body, which is of long, easily drawn outline, is of 5 pasenger nominal capacity, with sufficient additional room in the tonneau for a couple of extra seats. Such relatively minor matters as fender and running board design, upholstery and body trim—the latter being of Circassion walnut wherever exposed—have been followed out in close detail.

Paris Salon to be a Tandem of Shows.

The Paris Salon this year practically will be two successive shows, with a week's intermission between the two. The expense of erecting a huge temporary building, as the growth of the industry made necessary for the salons of the past two years has been the determining factor in the change. Instead of holding the exhibition of industrial motor vehicles, motor boats and allied industries coincidentally with the show of pleasure cars, motorcycles, bicycles and accessories, the latter will open on November 28th and continue until December 13th, in the Grand Palais on the Champs Elysees. Following its close the Palais will be prepared for what practically will be a second section of the salon, opening December 22d and closing December 29th, at which industrial exhibits will be seen.

Maine's Income from Registration.

According to figures given out at the office of the Secretary of State, of Maine, the sum of $1,110 was received for automobile registration for six months ending July 1st of this year. For the same period the receipts from operators' licenses were a little in excess of the amount received for vehicles, being $1,208. Dealers' licenses added $180, and from registration of motorcycles came $126; making a grand total for six months of $2,624. The fee charged for the registering of automobiles and motorcycles and licenses to operators is $2. and for dealers' license $10.

Firestone Shows Its Credentials.

An instructive pictorial display of the commercial vehicle branch of the industry is afforded by a booklet of testimonial letters just issued by the Firestone Tire & Rubber Co., Akron. O., and containing illustrations of some 40-odd vehicles of different manufacture and different purpose, suggestively arranged. The accompanying letters, of course, sing the praises of the side-wire tire under various conditions of use. The latter portion of the book is devoted to similar matter, relating to the use of these tires for fire apparatus.

How One City Official Gets His Car.

Usualiy the purchase of a motor car by a municipality involves the making of a special appropriation for the purpose. The city electrician of Cambridge, Mass., however, has evolved a method by which an automobile may be obtained without any action by the financial committees of his city. He has brought about economies in the administration of the affairs of his department and by so doing has saved enough money to pay for a motor car.

Specifications common to all Palmer-Singer models

Nickel steel throughout. Imported F. & S. ball bearings exclusively. Bosch high-tension magnetos and Multiple disc clutches in all models. Nickel steel, double and single drop frames. Drop forged I beam, nickel steel front axle—four-speed selective type, sliding gear transmission with direct drive on third speed. All brakes equalized, all expanding type and on rear wheels. Universal joints on all steering connections. All types shaft-driven, all moving parts inclosed in dust-proof cases.

FEEDS FUEL ON STEEPEST GRADES

Ramblers Now Equipped with Supplementary Tank—Furnishes Independent Flow of Gasolene in Emergency.

Years ago—that is about 10 years ago—it was not an unusual sight to see automobiles going backward up steep hills. The reason for this mode of crab like travel lay in the fact that many gravity tanks were so situated in the machine that the incline of the car on steep ascents placed the carburetter above the level of the gasolene with the obvious result that the fuel was not fed into the mixing chamber. Later designs largely overcame this defect, but even to-day it sometimes happens that on very steep hills, when the gasolene supply is low, the fuel cannot run by gravity to the carburetter.

RAMBLER ENGINE, SHOWING SUPPLEMENTARY GASOLENE TANK

With the knowledge of this condition, Thomas B. Jeffery & Co. now are building their Ramblers with a supplementary gasolene tank located above and behind the carburetter, considerably below the main gasolene tank. This supplementary tank will carry sufficient gasolene to run a car several miles up grade and is so arranged that it will flow into the carburetter on level or on a slight upgrade, but will not, under any condition, run back into the principal supply tank. The measurements of the tank are 4 inches in diameter and 10 inches long.

Costliness of Using Inferior Oil.

Economy in cylinder oil, either in its sparing use or in the purchase of grades which are chosen because of their cheapness, is a policy involving the error of "penny wise and pound foolish" action, according to H. E. Haws, of the George A. Haws Co., which manufactures Panhard oil.

"The importance of lubrication is not half appreciated," he says. "It is surprising how many will try to economize by buying inferior oils when the cost of lubrication is so insignificant as compared to the general cost of maintaining a motor car. There is no surer method of ruining a fine engine than by the use of an inferior lubricant and this policy of buying cheap oils is particularly foolish when a really high-grade oil can be bought for only a few cents a gallon more. It is a mistaken idea to suppose that all grades of oil are suitable for all grades of cars. We have gone into the subject pretty carefully and as a result of our experiences and tests, we like to recommend to a customer that particular kind of oil best suited to his motor."

Hub Caps that Require Watching.

Because of the small amount of attention which the wheels of the modern car ordinarily require, the average driver is apt to neglect to give them the necessary inspection. In many machines the hub cap is of no importance save as a dust protector and ornament. In machines having the rear floating axle drive, however, it is of the greatest use, since its removal releases the so-called hub-cap drive, freeing the wheel, and further rendering it possible for the driving stub of the differential shaft to work out, with consequent possibility of grave damage to the driving mechanism. On this account the condition of the caps should be watched very closely, and wherever possible, they should be secured from turning by means of locking screws set radially into the hub.

SIMPLY "A SUBSTITUTE FOR LEGS"

So Eames Defines the Electric Vehicle—He Estimates Its Mileage Capacity as of Neutral Importance.

Mere mileage capacity in its relation to the value of electric vehicles, a subject which was discussed at some length in the Motor World not a great while ago, is greatly over-estimated in its importance according to Hayden Eames, of the Studebaker Automobile Co., who concurs in regarding great mileage as a neutral recommendation by reason of other conditions which it implies. "A substitute for legs" is what he denominates the electric vehicle, and suggests that efforts to give it long distance abilities are generally attended with certain definite drawbacks which the average user cannot afford to overlook.

"We are hearing a good deal about electric vehicle mileage runs," he says. "Why is the unhappy public inflicted with a fresh outbreak of this kind of 'special performance'? Five or six years ago an electric car won a 185 mile race in France over competitors of all kinds. This was easily done, but the car was unfit for general use. It is not generally known that up to some six or seven years ago, the fastest automobile mile was made by an electric. The first road vehicle to make a mile a minute, was an electric automobile, but none of these qualities make for serviceability. An electric open vehicle is not supposed to do touring car or race track service.

"Anyone who buys an electric vehicle in comparison with a gasolene touring car must be misinformed, or at least fails to understand their respective applications. The sole ordinary application for an electric pleasure vehicle, is as a substitute for legs. It is strictly a convenience, and it should be designed with reference thereto. In these days of convenient and semi-automatic individual charging equipment, a provision in the design of an electric vehicle for mileage in excess of that required in its proper application, is simply wasted, and a positive disadvantage to the customer. Why should he be compelled to pay for a power plant to carry around a couple of hundred pounds more battery than he can possibly use? Why should he be compelled to maintain and renew 100 or 150 more plates of battery than he can possibly use?

"It is only by the addition of battery that additional mileage can be obtained without some other sacrifice. There are no mysteries to-day about the practical design of electric motors, of running gears, or even of storage batteries. Of speed and mileage there must be enough, but the popular conception that these have no limits of desirability, is entirely erroneous. The point is to design an electric automatic which best serves as a substitute for legs."

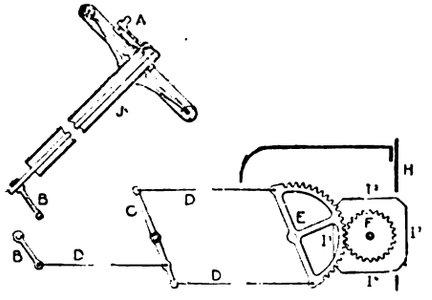
ABOUT FRICTION TRANSMISSION

Where Watchful Care is Required to Maintain Its Efficiency—Some Errors to be Avoided in Driving.

While the average friction transmission is so simple as to require small attention in the way of upkeep, there is one point about it which should be watched with extreme care. In case the driving and driven shafts become disaligned, even though by a very slight amount, the effect will be to distort the pressure angle, bring the driving strains outside the plane of the disc, and besides tending to warp that member, cause uneven wear on the surfaces and reduce the amount of surface in actual contact at the driving point.



Another source of difficulty occasionally arises when the two shafts are warped or otherwise thrown out of the same plane so that the point of contact lies either above or below the center line of the shafts. In this case there is a tendency for the driven disc to creep either in or out on the driving member, tending to increase or diminish the speed of the car as the case may be, and, if this tendency is resisted by the locking device on the speed changing lever, proportionately increasing the strain in that quarter. In fact this matter of alignment, together with the need of keeping the working surfaces clean and in proper condition, involve all there is in the upkeep of this type of driving mechanism, except the lubrication of the shaft bearings.

While the extreme flexibility of the friction transmission is its greatest asset, care should be taken not to abuse this quality by too frequent use of the speed changing lever for braking purposes, or by attempting to change speeds too abruptly without altering the speed of the motor temporarily in order to "nurse" the gear into driving contact with as little slipping as is possible—as must be done with the ordinary type of sliding gear transmission. These practices cause undue slipping at the point of contact, with consequent abortive wear. The result is a reduction in the life of the parts, unsatisfactory service, and a general tendency to lose confidence in the effectiveness of the system.

Devices to Warn the Car Behind.

For the purpose of warning drivers of following vehicles of proposed manoeuvres on the part of the driver of a car, several different indicators have been devised. In the simplest of these, the mere act of declutching, causes a semaphore to be dropped automatically at the back of the car, thus exposing a sign with the word "Stop," printed on it. In others, the movement of the steering gear causes the indicator to announce the direction of a proposed turn. A recent French contrivance, which has been placed on the market by the Box Garage, a Parisian concern, however, differs from any of these in that it also provides a warning, as well as the stopping and turning signals, while, like at least one other which has been designed, it is operated manually, instead of by automatic means.

The mechanism by which this result is arrived at is sufficiently simple to be worthy of note, although it possesses the drawback of adding to the already over-complicated mechanism connected with the steering column. As shown in the accompanying illustration, the lever, A, which is mounted on the steering wheel beside the usual spark and throttle levers, is connected through a Bowden wire mechanism with a second lever, C, which, in turn, is connected to the sector, E, engaging with a pinion F, on the

indicator, I. By moving the lever into one or another of the four notches which are provided on its segment, the faces 1-2-3-4, on the indicator may be brought successively into registry with an opening in the back of the casing enclosing the mechanism, thus exposing them to view.

As used in France, the indications thus made available correspond to "Attention," "Stop," "Right Turn," and "Left Turn." The device is so contrived, however, that by a very slight alteration in its arrangement a greater number of signals could be employed, if so desired. Systems of this sort, while useful, especially for machines which are to be run extensively through closely crowded city traffic, lose something in value when they are not absolutely automatic, for otherwise their efficiency depends entirely upon the fidelity of the driver in actuating them. The value of this point is emphasized when it is further considered that when such a device is most needed, is usually at a time when the driver himself is fully occupied in taking care of some sudden emergency. At the same time, the arrangement here shown is sufficiently simple to be of some little suggestive value.

Keep the Fan Bearing in Condition.

Frequent attention should be paid to the condition of the fan bearing and its supporting bracket. Should they be permitted to become loose enough to throw the fan out of line, there is danger that it will scrape against the back of the radiator, tearing away the thin walls of the structure and doing an amount of damage which is totally disproportionate to the original difficulty.

IMPORTANT QUALITIES IN VARNISH

Special Requirements for Automobile Body Finish—An Expert Specifies Some Indispensable Characteristics.

How far the much desired richness of finish which characterizes the well made automobile body may be due to the use of a suitable varnish, the average user probably is not at all aware. That a considerable proportion of the lustre is obtained by properly skilled treatment, goes without saying. The important part played by the material itself, however, may be judged by the following requirements which have been set down by an expert:

"Working properties of varnish, its capability for working free and rich, and without a hitch in its power for flowing unrestrained over the widest expanse of surface, appeal to the user of the material, first of all," as he observes.

"The varnish that manages to meet the measure of working property demanded in the horse-drawn vehicle paint shop, may, and, indeed, frequently does, fail to satisfy the varnisher working over the automobile surface. It becomes lame, and 'sets up,' and refuses to work properly over the full expanse of the surface. Manifestly, such a varnish is ill adapted to the needs of the automobile finisher. And yet, contrawise, the varnish must have the gift of drying free from dust over night in apartments not invariably heated as the varnish maker suggests, or as the prudence of the painter would ordain. And to these virtues must be added that of fine brilliancy, with a richness of lustre, in fact, that goes down to the root of things and sets forth unmistakably all the deficiencies, big or little, which a careless or incompetent workman may have strewed in the way. Then there must be toughness of fiber, once the varnish has flowed to its position on the surface, and through the process of drying fastened itself there. And to toughness of fiber we must add elasticity, and its twin virtue, resiliency. For to meet the tremendous strain imposed upon the automobile surface, these properties must be present in varnish to an unbounded extent.

"Imperishability, that quality in varnish which protects its exposed film from the ravages of a thousand enemies, atmospheric and existing in the atmosphere, is another essential indispensable to the composition of the best automobile varnish."

To remove grease spots from the carriage cushion, wet the cloth with clean water and a sponge with a mixture ¾ ounce table salt and 2 ounces alcohol, either grain or wood. The time-honored recipe for revamping leather upholstery is raw linseed oil and turpentine used in the ratio of about 2 to 1.

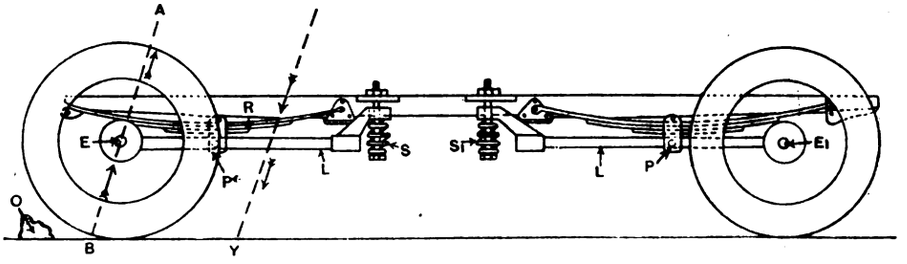
ANATOMICAL IDEA IN SUSPENSION

Principle of the Human Foot Adopted in New Foreign System—Details of the Method of Application.

It is generally recognized that the all-important question of tire wear is dependent to a very large extent upon the method of design and construction of the spring suspension. The possibility of ameliorating the expense due to this cause by improving the suspension of the body has long been appreciated, but the difficulty of discovering a proper method of attack is a stumbling block which is as equally appreciated. Interesting light is thrown on the matter by the Autocar which introduces the analogy of the human foot and its mechanical structure, in what is virtually a brief for the Victoria suspension a system which has seen some little use in England, and is well worth considering for its own sake. As a contribution to a difficult subject and one which is none too well understood, it is of further value.

By way of fundamental definition the author indicates that the broad question of suspension comprises a proper consideration of two basic and opposed factors, that is to say, "the weight of the chassis, body, and passengers, on the one hand, and the various road resistances on the other. Between the two," he continues, "is the tractive or rolling medium—the wheels. But, on the one hand, for the sake of traction efficiency, we must keep the wheels in as continuous contact with the road surface as possible. On the other, we must protect the chassis and its load from the road shocks. So it follows that we must introduce some elastic medium between wheels and chassis to secure their mutual independence as far as possible. . . . .

" . . . . In all conventional systems this elastic medium—to wit, the springs—is so introduced that the forces of chassis weight and road resistance are maintained in direct opposition, the lines of force being directly opposed along the same plane. Consequently, the action of the suspension—which is exactly that of a rubber pad or spring, set in a wooden leg to deaden the shock—does not alter the permanent relation of the opposed forces along that plane in the slightest. This fact alone almost suffices to prevent the desired independence of chassis and wheels, even with three point suspension, and certainly restricts the function of the springs to that of mere intermediate buffers, and a further consequence is that the very resilience of the suspension which gives it a receptive action gives it a rebounding one, which, occurring, as it must, along that single line of opposed forces, further restricts independence. Thus, we have that leaping 'hunting' action set up, which is naturally fatal to keeping the tires on the road surface at a continuous and even pressure. And it is just the failure to do this that is the chief factor of tire destruction.



"So having seen in detail why conventional suspension systems fail to secure the independence of chassis and wheels, ... we must cast about for another method of dealing with the opposed forces. And the mechanics of the wooden leg having failed, what more natural than to consider those of the normal human foot, as in walking or coming to the ground after jumping?

"Now in this case, we have our forces balanced, instead of in direct opposition. That is to say, we have the stationary force (ground resistance) taken at the toe, which, with its joint, serves as an articulated point of adhesion—a fulcrum, in other words—for a rigid lever formed by the length of the foot. This lever supports the other opposed force—the weight of the body—somewhere about mid-length, and is enabled to do this by means of an elastic medium—the calf muscles—which are attached to the other end of the lever—the heel—as well as to the body, in both cases behind the line of the descending force.

"Actually that line bisects the lever midway, so, since the extent to which the body (force or weight) descends is regulated by the degree of muscular relaxation, it is clear that the two opposed forces are balanced at an oscillation point, floating, as it were, somewhere between their parallel opposed planes. It will also be obvious that, although the oscillation point never shifts, the extent of the lever oscillation can be varied to suit the strength of the opposed forces, because they are thus balanced. Also, that while the lines of force always maintain their parallel, they are free to approach or recede from each other, according to circumstances, in perfect independence because of this balancing. That is to say, their balance and independenct relation is unaffected, although the foot—the lever—be more or less extended or flexed according to the length of the step taken or the height jumpd from.

"So much for the mechanics of the matter; yet when we examine the results of its action we see that the point of adhesion—the toe—even when unshod, suffers no abrasion; nor, on the other hand, does the descending weight sustain any shock or vibration. But this, we remark, is the exact opposite of the results noticed in the action of the rubber padded wooden leg, in which the vibration is only lessened by the resilience of the rubber upon which the wear is consequently excessive.

"Now this compression of results, as applied to chassis suspension, certainly argues strongly in favor of the system of balancing the opposed forces, road resistance and chassis weight, upon, so to say, a floating oscillation point, as the true solution of the problem of tire maintenance. For it is clear that the independent relation of opposed forces thus obtained not only checks vibration and the transmission of road shocks, but also enables the tire at the point of adhesion to the road surface to maintain a constant and even pressure thereon, following all its contours. Therefore it follows that in the same degree as the failure of other suspension systems in this regard destroys the tires, the success of this one must preserve them.

"Hence the Victoria Suspension, invented by M. C. E. Kolb, 36 Rue de l'Arcade, which achieves all these results by a mechanical action exactly similar to that of the human foot, is not only extraordinarily interesting, but from its success in practice—as shown by a tour of several thousands of miles with a single set of tires which finished practically unworn—may be regarded as the most serious effort yet made to solve the tire upkeep problem in a mechanically accurate manner. For, as will be seen from the accompanying illustration of this system, the chassis and its springs are mounted, not upon the axles E-E1 direct, but in rocking joint P upon a tubular or pressed steel lever L, which is articulated to the axle E in a rocking joint at one end and supported at the other by the spring S, depending from the side member of the chassis. Thus the upward line of force of the road resistance A B is balanced against the downward line of force of the chassis weight X-Y at or near the oscillation point P.

"Now, when any one of the wheels meets any obstacle such as O, it naturally rises to surmount it, and in so doing would tend to compress the flat spring R and lift the chassis. Actually, however, this action is nullified, the spring R only acting as a shock absorber and supporter of the chassis. For the moment the effort or shock of the wheel rising occurs it takes effect upon the lever L, which oscillates at the point P, the weight of the chassis acting on the line of force X-Y to depress L against the pressure of the spring S or S1 at the other end. Consequently, the opposing forces of obstacle resistance and chassis weight are

Digitized by Google

taken through the lever L by the opposed springs R and S, which compensate each other's action, and being thus deadened and nullified, the result is that the chassis is neither raised nor lowered. Thus the effect of shock and vibration is lost entirely, and the displacement of the axle E being entirely compensated by the action of the opposed springs, the tire and wheel simply roll over the obstacle at an unvaried pressure, absolutely independent of the chassis motion. The same result, of course, occurs when the wheel drops into a depression or hole in the road, the only difference in the action of the opposed springs being that the oscillation of the lever L releases the compression upon each simultaneously to an equal degree, the final result being the same in each case.

"But the achievement of absolute independence in the motion of chassis and wheels naturally connotes the elimination of all torsional strains. But a further interesting result of this system of suspension is that, although the wheelbase is lengthened some 60 c. m., the chassis is relatively better supported towards the middle than a chassis of equivalent wheel base suspended in the ordinary way. This, although the whole of its weight lies between the axles. . . . .

"It follows, then, from the foregoing results that the speed at which it is competent to employ solid or semi-solid tires instead of pneumatics is augmented from 30 per cent. to something not far short of 50 per cent., according to the weight of the chassis and body. Thus not only is the average touring car of medium weight driven at average touring speeds brought within the scope of solid tire usage, but an entirely new field of employment—and consequently an enhanced demand—is provided for a whole host of lighter vehicles, all because of the economy thus effected in tire maintenance. . . . .

"Here it may fittingly be pointed out that this suspension entails no special construction, but may be applied to any existing car by lengthening the shafting forward or aft of the gear box, according to whether chains or propeller-shaft transmission is used, together with an approximate lengthening of the brake rods, the fitting of suitably shaped hangers to the side members to take the middle springs, and the slight adaptation of the axles to take the rocking joints of the suspension levers. The whole conversion, in fact, should not cost more than $100 or $125, and should save its cost in tires in a year."

It should be understood, as he explains in conclusion, that his purpose is not to suggest the elimination of the excellent pneumatic, or to lessen the demand for it. Relative to this point he says that "on the contrary, it is intended to demonstrate a system whereby the innate good qualities of the pneumatic—now almost rendered latent by its defects—may be brought out to the fullest by the elimination of those defects."

SUGGESTS PERPETUAL MOTION

Philadelphia Inventor Makes Big Claims for New Motor—Carbonic Acid Gas Employed to Generate Power.

World-beating motors have appeared before now, but none, so far as is known, for which is claimed an output of anything like 100 horsepower from three cylinders, each measuring two inches bore and stroke—which is the claim advanced for the product of John Carroll, of Philadelphia, Pa., whose achievement is further signalized by the fact that it is actuated by the expansive force of carbonic acid gas. Although it is said that Carroll's efforts at perfecting this prodigy in miniature have extended over the past eleven years, it was not until early this week that they were sufficiently successful to permit of a public demonstration of the motor. At that time, mounted in the chassis of a well known make of small runabout, it proved to be perfectly competent to propel the machine over the paved streets of the city and up one or two trial hills.

While hints have been dropped from time to time to the effect that something of the sort was in progress, the extent of the exploitation contemplated was not suspected until the time of the demonstration, when it was announced that arrangements already are in progress to secure factory facilities for the production of cars propelled by the new motor, all of which are to be built in the City of Brotherly Love. It was further stated in the same connection that work upon them will be commenced immediately so that the cars can be ready to market in the fall. At present, the experimental work is being conducted in a shop in Filbert street, while the offices of the company are in South Penn Square.

Although the exact details of the invention are lacking, it is made to appear that the marvelous nature of the motor is not confined to its apparently disproportionate power production. From newspaper reports it is learned that its cylinder dimensions are 2 by 2 inches, as above stated; that each cylinder carries two pistons working in opposite directions and connected to the crank shaft through suitable linkages, and that the main portion of the device is cut from a solid piece of steel, its outside dimensions being 13½ by 10½ by 4½ inches, as well as that it is capable of developing no less than 100 horsepower. The valve motion is connected by direct and unvarying gearing, it is said, while the power and speed control is vested entirely in a hand throttle—no change speed gearing being required.

The truly wonderful part of the invention, however, is explained in the following paragraph, revealing a cycle of operations which, if the matter is not merely a dream, should cause the ingenious Carnot to turn in his grave:

"The power is furnished by a small tank which is filled with carbonic acid gas. This tank is connected with the engine, the gas going to the engine through a small copper tube about as thick as a lead pencil. When the gas has gone through the engine it goes back into an exhaust tank after passthrough which it is recondensed and flows into the first tank from which it originally came. In addition to these two tanks, there is an auxiliary tank for conveying an extra supply of carbonic acid.

"There is no light or heat about the Carroll motor," continues the description, "and therefore it cannot burn out or freeze. It can be run anywhere on the hottest or the coldest day. A chemical solution, which Mr. Carroll says is mostly coal oil, is used in the tanks to prevent the possibility of corrosion or oxidation."

If, as is implied by this, the gas is recondensed and returned to the original supply tank by the 13½ by 10½ by 4½ motor or some of its appended mechanism, it will be observed that an approximation to the long-sought perpetual motion has at length been achieved, since the process of recondensing the gas gives to it a supply of energy which was withdrawn previously by its expansion in the cylinders. This would constitute a marked improvement over the original proposition in connection with the use of carbonic acid gas, which was, to have the tanks charged at regular supply stations, very much as storage batteries now are charged for electric vehicle use.

Among other advances embodied in this contrivance, may be mentioned its economy of upkeep. Besides being so simple that a ten-year-old child can operate it successfully, it requires so small an amount of oil that it need not be lubricated oftener than once a month. In consequence of this and other factors, Mr. Carrol is credited with the estimate that "anyone owning one of these cars could take five or seven persons to Chicago for less than one dollar"—though it is not specifically stated whether such a journey would be from Philadelphia to Chicago, or from Evanston, Elgin, or some other less remote point.

Various Causes of Noisy Running.

An occasional source of noisy running in a car which has seen considerable use is a leaky condition of the various joints in the manifold and exhaust piping. This may be due to one of several causes. The muffler supports may have become loosened sufficiently to permit a slight amount of play; disalignment in the piping also may have been set up. A third cause of difficulty may be due to the blowing out of the asbestos packing in the gaskets, while warped flanges in the couplings, a choked muffler or a kinked outlet pipe also may be responsible for the condition—which in any event, should be remedied at once.

AUTOMOBILE AS A FARM WAGON

How One Progressive Farmer Makes His Pleasure Vehicle Useful—Finds It Saves Time and Expense.

Chickens, milk cans, bags of grain, tools, young trees, the purchases in town, and any number of other things go to make up the loads that the busy farmer's automobile is called upon to carry during the course of the day. That type of agriculturalist who combines enterprise and business sense with an ability to run a farm profitably is proving a great friend of the industry and a good customer. It is no longer merely the city dabbler in "gentleman farming"—whose products are scanty and whose milk costs him more than champagne—that affects the motor car, but the more practical money makers, who are alive and keen for everything that will help them in their business.

MODERN FARMER STARTING ON TRIP TO TOWN

In addition to the special types of machines that have been designed particularly for the farmers' trade, there are several of the more "cityfied" style which have found favor because of their generous carrying capacity, their reliable running and their low cost of upkeep. The accompanying illustration shows a Rambler car in actual service on a farm, where for some time it has been proving itself more than worth several teams. The big dinner bell in the picture testifies as to its being a real farm, and the load on the back was not put there by a press agent.

The owner of the farm and the machine, in addition to tilling the soil, is quite a horseman, both as a driver and a breeder. Nevertheless he does not permit any maudlin sentiment over the horse to interfere with his enjoyment of the economical advantages in time and money which the motor car offers him as a means of transportation around the farm itself and in trips to and from town.

Movement to Aid International Travel.

With the laudable object of determining means "to regulate and facilitate automobile traffic from one country to another," M. Pichon, foreign minister of France, has proposed the convocationof an international conference to be held in Paris, probably in October and in conjunction with the International Road Congress to be held at that time. The movement is said to have originated through M. Barthou, minister of public works, on whom falls the burden of providing the necessary permits to drivers, both domestic and foreign, and who has been constantly pestered with appeals to relent in the excessive use of official red tape in this respect.

Whatever may be the difficulty incident to the various registration laws of the different States of the Union in respect to interstate motor traffic, motorists touring abroad are subject to even greater vexations owing to the lack of uniformity of the regulations of different countries, and to the great amount of time which must be consumed in complying with the necessary formalities. Obviously, an agreement for the universal recognition of driving permits such as is contemplated would be a matter of such great convenience as to be worthy of whatever consideration it may receive.

NEARING A GREAT LEGAL BATTLE

Former Governor Briggs to Lead Attack on New Jersey's Oppressive Law—He Considers It Unconstitutional.

Former Governor John W. Griggs, of New Jersey, has been engaged as chief counsel in proceedings begun by the motorists of that State to test the validity of the motor vehicle law distinguished by the name of Senator Frelinghuysen, the New York member of the New Jersey legislature. Prof. Charles Thaddeus Terry, of the Columbia University Law School, who is counsel of the National Association of Automobile Manufacturers and chairman of the A. A. A. legislative board, will be associated with Mr. Griggs in the suit that will soon be brought to test the constitutionality of the New Jersey automobile law.

The fight against the oppressive law will be made under the joint auspices of the Associated Automobile Clubs of New Jersey, the State organization of motorists, and the New Jersey Automobile Trade Association, in which are included practically all of the automobile agents, tire accessory dealers and garage keepers of the State.

It is Mr. Griggs' opinion that the present New Jersey motor vehicle law is unconstitutional and he believes it will be set aside by the United States courts.

Division Threatened in New Jersey.

As a result of dissatisfaction growing out of the management of State and National affairs by the Associated Clubs of New Jersey—an organization which was formed as a federation of the motor clubs of the State—the New Jersey Automobile and Motor Club is considering the advisability of withdrawing from the State organization. The question of withdrawal will be definitely settled at a meeting of the trustees of the club to be held to-night (Thursday). It is understood that the contemplated withdrawal does not preface a severance of relations with the American Automobile Association, despite a press rumor that such a move is contemplated.

That the New Jersey Automobile and Motor Club has not taken a more prominent part in the Associated Clubs' doings before, it is learned, is because its officials wished to give the smaller clubs every representation possible.

The action of the Associated Clubs last week in retaining John W. Griggs, former Governor of New Jersey, to bring suit to test the constitutionality of the New Jersey law is regarded as futile by many members of the Newark club, which has stood for a policy of construction rather than destruction, and tends to favor the expending of effort and money on the preparation of a model law to be introduced in the legislature next year.

PROBLEM OF THE WASTED ENERGY

Solution Made Difficult by Limited Size of Engine—Shortcomings of Varied Attempts to Reach It.

It is a safe assumption that no one who has given the matter much thought has failed to recognize the desirability of economizing a certain proportion of the energy which ordinarily goes to waste in the internal combustion motor. Knowing that the purpose of the engine is to convert heat into work, and observing the amount of heat which is lost in the radiator and through the exhaust, it is perfectly natural to wonder why it is that so much energy is lost, and why efforts are not made to utilize this great amount of actual and appreciable waste.

As a matter of fact, this subject has attracted inventors and engineers for many years, and as the result of their labors a large number of schemes have been proposed for utilizing the waste, or what is the same thing, gaining added power from the same amount of energy developed in the gas. Just why none of these schemes have come into practical fulfilment, is another matter. In general, however, it may be said, that for motors of low power and necessarily compact construction, such as those of the automobile type, the power gained by the form of "economizer" chosen, is mostly absorbed in the added friction of the extra parts necessary to develop it, while the remainder is not of sufficient magnitude to warrant the additional weight and cost of the parts involved.

Many such systems are very fascinating in theory, at least, and in some instances, if applied to large power plants, might work sufficient saving to warrant their use. For the small motor, however, practically none have yet proved available in the broadest sense.

While the internal combustion motor is recognized as the most economical form of heat engine yet produced, speaking entirely from the standpoint of thermal values, the fact remains that its sources of waste energy are so evident as to attract the attention of even the non-technical observer in a way to provoke no small amount of wonder that they have never been reduced to lower terms. Thus, where in the steam power plant, the losses of energy due to heat radiation are distributed over the entire plant, beginning with the fire box and ending with the exhaust steam piping, or, perhaps, with the condensing mechanism, in the gas engine, the radiation loss occurs entirely in the cylinder itself. Where in the steam engine, it is customary, at least in large plants, to condense the exhaust steam, thereby adding to the power of the engine, in the gas engine the amount of energy thrown to waste through the exhaust is well advertised by the noise and by the special means which must be taken in order to suppress it. Nearly every one who has ever come into contact with gas engines, probably has reflected on the magnitude of these two losses, and has attempted to devise means of reducing them, or if not that, finds it difficult to understand why such means are not applied more generally.

The inevitable reflection when the motor fails to develop the required amount of power is, why must all this heat and power be lost? Why not use some of it, if not all, exactly as it has already been used in the engine? This idea of using over the exhaust, that is to say, "compounding," is one which received considerable attention a few years ago, with the result that at least two types of compound engine were designed. One such is still upon the American market, and has been proved to be economical of fuel, and to afford a good ratio of weight to power output. In all fairness, however, it must be admitted that a four-cylinder motor of the ordinary type, developing the same amount of power, would be more economical to run in the sense of upkeep, because despite the fact that it possesses one more cylinder than the compound type, which, in the case in point is of the three-cylinder form, all the cylinders are of the same size, and therefore are perfectly interchangeable, with all their connecting parts. The more uniform torque of the quadruple, as contrasted with the triple type of motor, also tends to the same result. The saving in fuel which is brought about by compounding, is so small as to be negligible, when considered in dollars and cents, even though it has considerable significance when expressed in percentages.

From the direct use of the motor exhaust by taking advantage of its expansive force in the cylinder, it is an easy and natural step to a similar application of its energy in other ways. Working along this line, at least one inventor has attempted to apply the turbine principle, merely directing the exhaust into a casing containing a rotor of such form that it would absorb the energy from the waste gases, converting it into work, and simultaneously cooling them. The power output of the motor was to be added to in this way. Unfortunately for this scheme, the turbine principle is not understood sufficiently well, even yet, to make possible a really practical application for low powers. Furthermore, as the rate of speed of the simple turbine must be very high, in order to utilize power so developed, more or less elaborate systems of reduction gearing must be employed, which, with their added weight in the vehicle, and their added friction load on the machine, tend to reduce the effectiveness of the additional power secured.

A scheme which, other things being equal, should work to more purpose than this, was proposed a year or two ago when the idea of locating some sort of a thermo-pile in the muffler and taking advantage of the electric current it generated for ignition purposes, was broached. The thermo-pile, which is little known outside the laboratory, be it said, is a combination of metals arranged in layers of plates, alternately coupled together and so constituted that when subjected to changes of temperature, an electric current is generated. The temperature changes due to the successive discharges of hot exhaust gases and the intermediate period of cooling between them, were thought to be sufficient to generate a current which could be used for igniting the gas in the cylinders of the motor. Nothing further has been heard of this scheme.

Although a large proportion of the heat generated by the burning gas is lost through the exhaust, another very large amount is wasted through the cylinder walls, being carried off by the jacket water, in motors of the most familiar type. To so arrange the jackets and the circulation of the water that instead of merely heating the water, it should convert it into steam, the steam to be used in actuating a special cylinder or cylinders, is an idea which has lured more than one engineer. Within a short time, patents have been granted abroad on a system in which this very idea is put into effect—but in motors of large power and size only. While the heat obtainable in this way might be sufficient for the generation of ammonia gas or some other vapor which is given off at a relatively low temperature, it seems doubtful whether steam could be effectively generated in this way in sufficient quantities to be of real use in increasing the power of the main engine. Certainly from the standpoint of the automobile designer, the necessary apparatus would be too bulky to be of value.

From the standpoint of closest theory, it may be said that any methods such as the foregoing, which seek to utilize the waste from the engine, are not destined to be extremely successful except in the case of large machines, merely because they require additional "plant," and additional mechanism means additional weight and friction. The most effective way of cutting down losses, is in the engine itself, by permitting the gas to expand as much as possible before releasing it, perfecting the mechanical details of the apparatus so as to reduce friction, and arranging the cooling system so that the cylinders will be maintained at a uniform temperature under all circumstances.

Loose Bolts Mean Lost Motion.

It is important that the bolts securing the carburetter to the frame or the engine base be kept securely drawn up. Otherwise there is danger of an accession of lost motion sufficient to strain the connections of the intake pipe and cause them to leak. The result of this is that the mixture will be "upset," and the proper amount of suction cannot be obtained at the jet.

The Week's Patents.

12,787.—Reissue.—Acetylene Generator. Richard H. Weles, Kenosha, Wis., assignor to The Badger Brass Manufacturing Company, Kenosha, Wis., a Corporation of Wisconsin. Filed Nov. 19, 1904. Serial No. 233,540. Original No. 737,183, dated Aug. 25, 1903. Serial No. 130,537.

1. In an acetylene generator, the combination with a water chamber, of a generation chamber within and surrounded by said water chamber, a carbid receptacle within and wholly contained by said generation chamber, a water supply pipe extending across and through the upper end of said generation chamber and outside of the latter communicating freely with said water chamber, a water controlling valve communicating with said water supply pipe within the generation chamber and controlling and directing the flow of water therefrom to the underlying carbid receptacle, and a gas discharge pipe leading from said generation chamber, substantially as described.

886,506. Automobile. Henry K. Holsman, Chicago, Ill. Filed Feb. 8, 1907. Serial No. 356,393.

1. In an automobile, the combination with the running gears, of the steering wheel having its axle pivoted thereon, the body, and the steering wheel fender partly supported by the steering wheel and partly by the body so as to swing with the wheel.

886,508. Steering Device for Automobiles. Joseph Horat, LaFayette, Ind. Filed Oct. 22, 1907. Serial No. 398,622.

A steering device for automobiles and like vehicles comprising an operating shaft provided at one end with exteriorly located threads, a sleeve surrounding the threaded portion of said operating shaft and adapted to be actuated thereby, racks secured to both sides of said sleeve, toothed segments adapted to engage the racks, means for adjusting the racks towards and from the segments, means for securing said racks, a rock shaft actuated by the segments, and a housing to envelop said steering device.

886,519. Internal Combustion Engine James B. Knickerbocker, Indianapolis, Ind., assignor of one-half to Thomas A. Conlee, Indianapolis, Ind. Filed May 31, 1905. Serial No. 263,056.

1. In an internal combustion engine, the combination with a cylinder and piston, of an inlet valve leading into the cylinder, a jacket surrounding the cylinder, and a communicating passage between said jacket and the inlet valve, said jacket being provided with a plurality of inlet openings through which the air supply for the engine will be sucked, the area of the inlet valve being greater than the total area of the openings leading into the air jacket.

886,520. Automobile. Emil Koeb, Leipsic, Ohio. Filed April 24, 1907. Serial No. 369,919.

1. In an automobile, the combination with the main frame, an axle pivotally connected thereto, and ground wheels carried by said axle, of an auxiliary frame secured to said axle and having one end adapted to move in a vertical plane, driving mechanism carried by said auxiliary frame, and means for operatively connecting said driving mechanism to said ground wheels.

886,523. Spark Plug for Explosion Engines. Ellsworth A. La Har, Forestville, Conn., assignor to John B. Smith, New Britain, Conn. Filed Aug. 30, 1907. Serial No. 390,844.

1. A spark plug comprising a holding socket, having an internal seat, a tubular cap for said socket, an insulator complete in itself and a middle sleeve permanently connected with the said complete insulator, the said sleeve being fitted within the said socket and to the said seat therein for holding the insulator in the socket through the said sleeve.

886,526. Carburetter. Walter L. Marr, Jackson, Mich. Filed April 9, 1906. Serial No. 310,685.

1. In a carburetter, the combination with a float chamber, a float in said chamber, and means operated by the float for admitting liquid to said chamber, of an air chamber extending downward within the float chamber and closed at its lower end and open for the admission of air at its upper end, a nozzle member extending upward within the axis of the air chamber, a tubular member extending laterally from the air chamber and forming a passage adapted to lead to the engine cylinder, a member within the air chamber extending across the same and forming a continuation of said passage, a tubular mixing chamber formed integral with said last named member and extending downward within the air chamber, and means for regulating the admission of air to the air chamber.

886,527. Carburetter. Walter L. Marr, Jackson, Mich. Filed April 20, 1906. Serial No. 312,768.

1. In a carburetter, the combination with a float chamber, and a float in said chamber, of a gasolene chamber, a restricted passage connecting said float and gasolene chambers, a mixing chamber within the axis of the gasolene chamber, and a nozzle in the axis of the mixing chamber in free communication with the gasolene chamber.

Motor-Vehicles

886,528. Motor Vehicle. Walter L. Marr, Jackson, Mich. Filed July 9, 1906. Serial No. 325,220.

1. The combination with the frame of a motor vehicle, of a motor supporting bed supported at one end upon the sides of said frame, means for pivotally supporting the opposite end of said bed to turn upon a horizontal axis extending longitudinally of the bed and yielding means at each side of said bed to resist its turning.

886,529. Explosion Motor. Armand Peugeot, Tony Huber, and Henri de Lostalot, Billàncourt, France. Filed May 6, 1907. Serial No. 372,259.

An explosion motor of two-stroke cycle comprising in combination a cylinder, a widened portion formed at the lower end of said cylinder, an opening formed in the widened portion of the cylinder, an admission opening formed in the middle part of the cylinder, a conduit connecting the said opening, a third opening formed in the cylinder for the escape of the gases, a sliding cover closing the cylinder immediately above the point where the piston stops, a hollow piston, an extension formed on the piston adapted to be surrounded and consequently cooled by the admission gases, and an admission valve arranged just opposite the opening formed in the widened portion of the cylinder, substantially as described and for the purpose set forth.

886,545. Carburetter. George M. Schebler, Indianapolis, Ind. Filed May 27, 1907. Serial No. 375,964.

1. In a carburetter, the combination, with the casing, having an air passage, a fuel nozzle in communication with said passage, and a fuel valve co-operating with said nozzle, of an automatic spring controlled air valve, a movable member coacting with the said fuel valve for moving the same, intermediate connections between said movable member and the air valve, and means co-operating with said intermediate connections, whereby the effect of the said movable member upon the fuel valve is varied at various points in the stroke of said movable member.

886,617. Vehicle Shock Absorbing Apparatus. Ralph M. Lovejoy, Meredith, N. H. Filed March 28. 1907. Serial No. 365,149.

1. Vehicle shock absorbing apparatus comprising a liquid chamber, an imperforate partition therein movable relatively thereto, means for connecting one of the said parts to the vehicle running gear and the other to the vehicle body, a buffer chamber, a liquid passageway connecting the liquid and buffer chambers, a valve in said passageway, and means for controlling the closing movement of said valve by the relative movement of the liquid chamber and partition.

886,938. Steering Gear. Alanson P. Brush, Detroit. Mich. Filed Jan. 30, 1907. Serial No. 354,813.

1. A steering mechanism comprising a steering shaft, a driven shaft in line with the steering shaft, an internal gear carried by the driven shaft, an external gear in mesh with the internal gear, an eccentric mounted upon the steering shaft to actuate the external gear, and means to hold the external gear from turning on its axis to cause the relative velocities of the steering and driven shafts to vary.

THE BALDWIN IMPROVED DETACHABLE CHAIN

is the best ever designed for automobiles. It is detachable at each link. The clip retaining the side links is not a spring, but a piece of soft metal that can be removed by spreading open, and replaced by closing with a pair of pinchers. It will not b eak, nor cut off, nor fall off. Firm as a riveted chain.

This chain is made in all sizes of the roller type.

Price the same as other chains.

NEW "WHITNEY" CHAIN BELT

For Cooling Fans, Oiling Devices, Motorcycles, Etc.

If you are not taking advantage of the Woodruff Patent System of Keying it will pay you to investigate.

Better results and a great saving in cost.

We carry 95 regular sizes of Keys and Cutters in stock for immediate delivery.

"Whitney" Patent Cotter Detachable Roller Chains

Made a fine record in the Briarcliff Road Race.

New York City, May 2, 1908.

THE WHITNEY MFG. COMPANY, Hartford, Conn.

Gentlemen—The uniform strength of an automobile driving chain is one of the important requisites in a speed contest.

The "Whitney" Chains which formed a part of the equipment on our three "Stearns" Cars in the recent Briarcliff Stock Car Road Race, showed their superiority by coming through this exceptionally difficult contest without the slightest evidence of the terrific strain which they had undergone. Our "Stearns" Cars made an exceptional showing in this race, and we attribute our success in no small degree to the entire absence of chain trouble.

Our experience in previous contests has taught us that a faulty chain can cause a lot of trouble.

We therefore take this opportunity to express the satisfaction which we feel at the manner in which "Whitney" Chains demonstrated their worth.

Yours very truly,
WYCKOFF, CHURCH & PARTRIDGE,
By C. F. Wyckoff, President.

THE WHITNEY MANUFACTURING COMPANY, Hartford, Conn.

Large Sales

make it possible for us to import **THE CELEBRATED BRAMPTON CHAINS** from **ENGLAND** (paying freight and duty), and sell them at the same price at which the several other automobile chains are sold to manufacturers, jobbers, dealers and users.

THE BRAMPTON MOTOR CHAIN

All side plates on both sides on the Brampton Chain are stamped **"BRAMPTON."**

LARGE SALES and SMALL PROFIT with thousands of satisfied customers is our best advertisement.

THE BRAMPTON CHAIN is made of helf-hardening Steel; the strongest Chain in the World. All parts polished; fits sprockets (that are properly cut) without friction.

Some of the other chains may look like **THE CELEBRATED BRAMPTON CHAIN** because some of the other chain makers began to copy the design and shape of the **BRAMPTON CHAIN** links in 1904. They have improved somewhat on their copied design from time to time until these chains now look more like the **BRAMPTON CHAIN** than ever before. These chains somewhat resemble the **BRAMPTON** in appearance, but the manufacturers of such chains have been unable to copy the material—self-hardening steel.

NO CHANGE IN THE BRAMPTON

There has been no change in the design, construction, material or finish of the **BRAMPTON MOTOR CHAIN** in the past ten years.—"ENUF SED."

PRICE

The price being equal, it's presumable you want the best, and full value for your money. In such cases, the **BRAMPTON FILLS THE BILL,** and the prices are the same to manufacturers, jobbers, dealers and consumers as any other chain of equal size—as follows:

CHAINS TO FIT AMERICAN CARS

1 x ⅜ x 9-16—1 x ½ x ⅝—1 x ½ x 9-16 roller ..... $1.00 per foot.
1 x ⅝ x ⅝ roller ..... 1.17 "
1¼ x ½ x ⅝—1¼ x ⅝ x ⅝—1¼ x ⅝ x ¾ roller ..... 1.25 "

We also carry in stock the **BRAMPTON CHAINS** to fit Foreign Cars—Mercedes, Panhard, Martini, Fiat, etc.

Your 1908 Car

You can have the new car that you order fitted with the **CELEBRATED BRAMPTON CHAIN** if you order it that way. No extra cost to either you or the manufacturer. All standard sizes in stock to fit American and Foreign Cars at the same price as the other chains.

SPECIAL CHAINS TO FIT THE INDIAN MOTORCYCLE.

Agents wanted in unoccupied territory. Catalog on request.

We are Sole American Agents for **BRAMPTON CHAINS,** and they cannot be bought from anyone else except through our Agents.

Pan-American Antomobile Body Polish

Pan-American Polish was awarded the Bronze Medal at the Louisiana Purchase Exposition at St. Louis, 1904. This polish has been carefully prepared for the Automobile trade. It is also applicable to the carriage trade, or can be used on any varnished furniture or woodwork of any kind. It will remove stains, cover scratches; leaves the automobile with its original new lustre, without being sticky or greasy. Furnished in eight-ounce bottles. Guaranteed not to harm the finest varnish. For sale by all Automobile Dealers. Price 60 cents per bottle.

The Miller Automobile Jack

The Miller Automobile Jack is a quick acting, automatic lowering jack, designed especially for automobile use, and is adapted to the factory or garage as well as to be carried as a part of the equipment on motor cars. It is high-grade and one of the finest finished jacks on the market. We guarantee this jack for twelve months. The list price of the Miller Jack, **$3.50 each.**

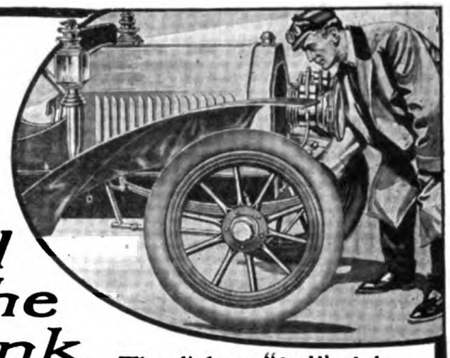
BEAR IN MIND

that in eight years there have been five models of Stevens-Duryea Cars. Worked out to perfection before being placed on the market — their mechanical features distinguished for being ahead of the times and because of common sense construction. Contrast the evolution of five unqualifiedly successful Stevens-Duryea Models with the every few months "improvement," radical changes, etc., in the output of some motor factories.

WHEN YOU BUY A STEVENS-DURYEA CAR YOU SECURE A MINIMUM OF UPKEEP EXPENSE AND A MAXIMUM OF PEACE OF MIND.



WRITE FOR DESCRIPTIVE MATTER

AJAX WRAPPED TREAD TIRES

After all is said
and done,
no matter how
glowing
the promises of
tire makers,
the only thing you have
to tie to
is
the word
of the dealer who
sells you.

If the tire
goes bad
you have the privilege
of carrying on
one end
of a controversy
with the factory—
that's all.

The tire maker
makes good—or doesn't
as he sees fit.

There's one exception—
AJAX—

Every AJAX tire
is guaranteed
for 5000 miles.

Write for copy of Guarantee, stating what size tire you are using.

EVERY CAR that is equipped with

GABRIEL EXHAUST HORNS
GABRIEL CUT OUT VALVES and
GABRIE SHOCK ABSORBERS

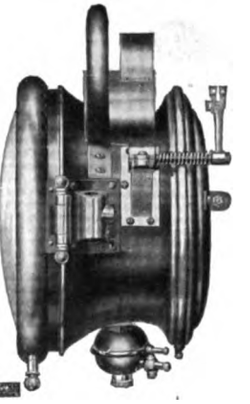
has at least three points of excellence.

Gabriel Exhaust Horns produce every tone from p. p. to f. f. in either one note or organ effect at will and carry the sound farther than the ear splitting "just as goods."

Gabriel Cut Out Valves relieve the engine of back pressure so that all power goes to the wheels—they help wonderfully in speeding, hill climbing and over bad going.

Gabriel Shock Absorbers take up every shock that is too great for the springs. All three easily attached to any car. Write for catalog and prices.

Gabriel Horn Mfg. Co. 1417 East 40th Street CLEVELAND, OHIO

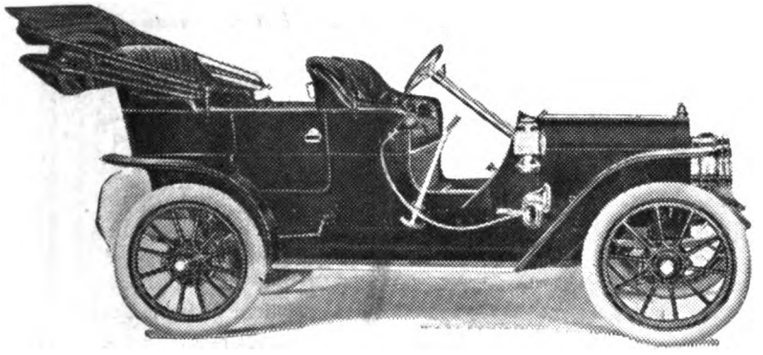


SOLARCLIPSE LAMPS

The Final Solution of the Lighting Problem is found in the

SOLARCLIPSE LAMP

This lamp throws two distinct rays—one of a far reaching, penetrating character, projecting a light over one thousand feet ahead, and the other a short focus ray which is thrown directly in front of the car.



The driver is at all times in perfect control of the lights. Through the simple manipulation of a dash-board switch the long distance ray may be suppressed or thrown on at will. The SOLARCLIPSE has greater light giving qualities than any other lamp.

Complete description of the Solarclipse Lamp and Besnard System of Lighting in our 1908 catalogue. Sent free upon request.

Warner Auto-Meter

GUARANTEED FOR ONE YEAR.

"Thirty Days' Free Trial"

When a manufacturer is willing to send his product to anyone, anywhere, for 30 days—with no deposit, no agreement to buy, no promise to do anything except give that product a fair trial—he must have more than ordinary confidence in his article. In order for him to have that confidence he must have a most extraordinary product.

That's what we do. We'll send an Auto-Meter to any automobile owner in the country—with no deposit, no agreement, no promise to do anything but put it on his car and give it a fair trial. It doesn't matter whether he has another make of speed indicator already on the car or not. Indeed, for the sake of comparison, we hope he has. We will abide by the decision—for he will always keep the indicator that tells the truth. We claim for the Auto-Meter that it is the only one of which "the dial never lies." We believe that the instrument itself is the most eloquent salesman we have—we're willing to let it do our talking. Send to-day just tell us what make and model of car you have size of tires, etc.—and we will send you an Auto-Meter.

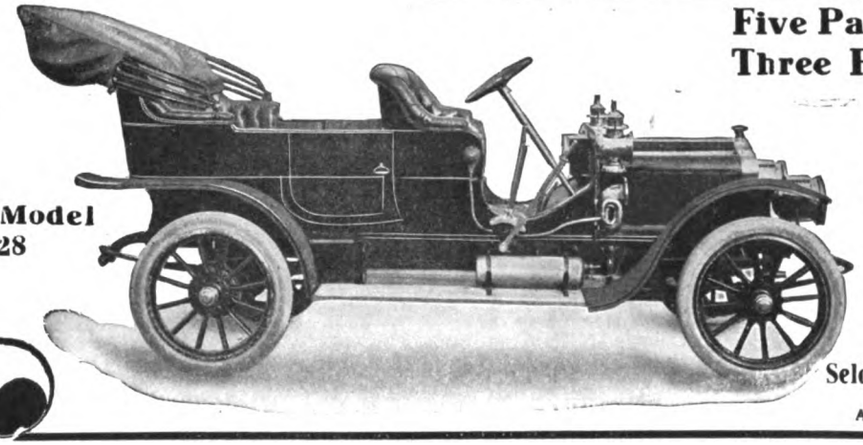
SUPPLEMENTARY SPIRAL SPRINGS

If every driver had to ride in his own tonneau, every car would be quickly equipped with Supplementary Spiral Springs. Owners are not intentionally selfish—many of them just thoughtless. Usually driving or sitting beside the driver, the riding qualities of the tonneau are to them practically unknown.



Not so with the passengers. Rear springs must be strong enough to resist severe shocks under a full load. That means stiff springs under ordinary loads, with the shocks and jars transmitted to the passengers—guests whose comfort ought to be a first consideration.

SUPPLEMENTARY SPIRAL SPRINGS take up all the average bumps and road inequalities and come into real action with the jolts and jars encountered at speed.

With the S. S. S., your springs never whip or touch. They prevent breakage and are the most economical and useful accessory ever provided for a car. Every live dealer carries them and their attachment is a matter of a few hours' time. Do it NOW.

Rambler

Model 31, Price $1,400

Other Models, $1,000 to $2,500

YOU can do all kinds of work with this car as a handy Runabout without the tonneau; then put the tonneau on and take your family or friends for a ride in a roomy Five-Passenger Touring Car.

Many exclusive features make it the most remarkable two-cylinder car in this country selling at $1,400.

The powerful engine makes it a hill climber; the long wheel and full elliptic springs provide great comfort; you glide over rough roads without a jar.

It is easy to care for and always clean because of the few moving parts and the enclosed power plant, impervious to dirt, mud and water, and oil tight with proper lubrication.

Immediate access to every working part is provided. The low cost of maintenance is due to simple construction, small fuel and oil consumption and protection of parts against injurious road material.

THE MOTOR WORLD

Volume XVIII. New York, U. S. A., Thursday, July 23, 1908. No. 17

SUES BANK FOR BUSINESS LOSSES

Allen-Kingston Wants $45,000 — Spent Money Advertising Cars That Were Never Delivered.

As a sequel to its relations with that troubled banker, promoter, sportsman, newspaper proprietor, automobile speeder, etc., E. Russell Thomas, the Allen-Kingston Motor Car Co. is suing in the New York Supreme Court for the return of $45,000 from the Consolidated National Bank and William O. Allison, Elverton R. Chapman and Thomas J. Lewis. The bill of complaint is such that the defendants made application to the court to have several of the allegations stricken out as scandalous, irrelevant and immaterial.

The trouble arises from the failure of the New York Car and Truck Co. to make and deliver cars to the Allen-Kingston Co., according to agreement. The Consolidated Bank and its officers, named as defendants, represented that the Truck company was a solvent concern, according to the complaint, instead of which it went into bankruptcy last March, leaving the Allen-Kingston Co. with its deliveries unfulfilled after the latter concern had spent considerable sums in advertising and salesmen's expenses.

An original contract, it is stated in the complaint, was made by Walter Allen on July 1, 1907, with the Kingston Motor Car Co., a Thomas property, for the delivery to Allen of 100 automobiles before April 15, 1908. Allen put up $15,850 as a deposit and then assigned his contract to the Allen-Kingston Motor Car Co., which was to sell the cars. The complaint says that E. Russell Thomas and Orlando F. Thomas gave Allen a guarantee at the start that the Kingston Motor Car Co. could deliver the goods, but that as it failed to do so beyond making six cars, it was proposed that the contract be turned over to the New York Car and Truck Co. for execution. Relying on the representations of the Consolidated Bank officials, the complaint recites, the plaintiff company and Allen agreed, on the distinct understanding that the bank was vouching for the financial responsibility of the Truck company. The latter concern was paid $17,000 for the six cars already made, and $9,150 was added to Allen's original deposit of $15,850, making a total deposit of $25,000 that the Allen-Kingston Co. had up on deposit, the complaint states. It further says that various advertising and other expenses were incurred to the extent of $11,500.

It is the $25,000 deposit, the $11,500 expenses and $10,000 in damages that the Allen-Kingston Co. seeks to get from the Consolidated Bank. A drawback of $1,500 on the six machines delivered is conceded by the plaintiffs. The complaint alleges that instead of being solvent and able to carry out such a contract as it undertook, the New York Car and Truck Co. was heavily in debt both to the Consolidated Bank and to the Hudson Trust Co., of which the defendant Chapman was president. It is also alleged that the bank owned a big block of the stock and was trying to help the company out of its difficulties.

One Chicago Show May Suffice.

Since the recent return of S. A. Miles from Europe the Chicago show situation's troubled waters have had hurried and liberal treatments of smoothing oil, and such vistas of concession and compromise have been opened that the likelihood of an "independent" show by the American Motor Car Manufacturers' Association has diminished almost to the vanishing point. N. H. Van Sicklen has been endeavoring to obtain the management of the latter show, but Miles is showing the possibility of all interests being well served in the one big affair, thus doing away with the necessity for two Chicago shows at this time.

A special meeting of the National Association of Automobile Manufacturers to discuss methods of space allotment will be held on August 5, at which time an all-day session is scheduled. Its results will probably quiet the two-show project.

PROMISE PROFITS IN "BLUE CABS"

Immense Taxicab Stock Flotation Backed by Prominent Men—Big Dividends on Ten Dollar Shares.

Practically the first extensive public promotion of a taxicab company in the United States is about to be undertaken by the American Taxameter Cab Co., with a capitalization of $1,500,000, divided into $10 shares on which dividends of 30 per cent. are unqualifiedly promised prospective investors. The company has an imposing array of names prominent both in the automobile trade and in general business, including F. D. Underwood, president of the Erie Railroad; A. F. Rockwell, president of the New Departure Mfg. Co., of Bristol, Conn., and of the Bristol Engineering Co.; W. B. Hurlburt, president of the Garford Motor Car Co., of New York; George W. Sweeney, president of the Hotel Victoria Co., New York, the La Fayette Hotel Co., Buffalo, and the National Hotel Co., Rochester; E. M. Tierney, president of the Hotel Marlborough Co., New York; F. E. Moskovics, well known in the automobile trade; James B. Coryell, president of the Cambria Coal Mining Co., Philadelphia; L. H. French, of New York, and T. H. McInnerney, of Rochester. These men constitute the board of directors, while McInnerney is president, and French, the vice-president. Offices have been established at 31 Union Square, New York.

"Blue cabs" are to be operated in New York, Chicago, Philadelphia and Washington. The machines are of the four-cylinder landaulette variety, seating four persons inside and two outside, and equipped with radiators for interior heating in the winter time. In addition to the regular taximeter service from hotels, restaurants, theaters, railway stations and the like, the company anticipates a large business from "the equipment of a number of chassis with special bodies, having the appearance of pri-

Digitized by Google

vate cars, to be rented to private parties by the week, month or season."

"It is the company's intention," the prospective investor is informed, "to declare no more than 30 per cent. dividend on the stock at the end of the first year's operations. Although the earnings of the company are expected to be sufficient to warrant a much greater amount, it is deemed wise to maintain a large surplus for the purchase of additional equipment. There could be no safer investment. The cabs earn as soon as in commission. The management of the company is in the hands of practical business men of long experience in this business. The element of chance is entirely eliminated."

The intending stock purchaser is advised that the cab is operated "at very small expense and the comparatively low tariff charged produces surprisingly large profits." The present taxicab service in New York is declared to be "wholly inadequate to the demand and in other large American cities no effort has been made to install such service. In New York City there are only two companies operating gasolene cabs for public hire on a large scale. Their profits are enormous and no stock in either company is for sale. American capital is at present invested in taximeter service in European cities, drawing phenomenal dividends, even though the tariffs are much lower and the number of cabs many times greater than here."

Original economies in equipment are promised by the fact that the company is to use cabs of American manufacture, thus avoiding the necessity for paying the 45 per cent. import duty that is imposed on the foreign cabs and parts such as the other companies use.

Elaborate tables of figures are presented to show on what calculations the expectation of steady 30 per cent. dividends is based. According to the data obtained, the cabs average 51 miles a day, with 2½ hours waiting time chargeable to patrons, giving an average gross receipt of $27 a day. Each cab need only earn $4.55 per day, gross, it is estimated, in order to pay all the fixed charges and expenses, to put aside 25 per cent. for depreciation on equipment, and to pay chauffeurs' percentage. "All earnings in excess of this amount are available for distribution as dividends," which on the $27 per day basis will yield 149 per cent. profit.

The plan of operation would be an investment of $800,000 in 400 cabs; $30,000 in garage and shop equipment; and $40,000 in repair parts. The annual fixed charges for operating expenses are set at $248,560 and the annual depreciation of 25 per cent. on the cabs themselves at $200,000, making a total of $448,560. The tire cost is figured on a contract basis of 2 cents per mile for 4 tires, by special arrangement with a tire company, so that no heavy investment in tires is involved. Following the usual taxicab practice, each chauffeur would furnish gasolene for his cab at his own expense, and would receive 20 per cent. of its gross earnings instead of wages. The operating expenses would include advertising, garage leases, oil, repair parts, shop equipment, all help, supplies, insurance, the bonding of chauffeurs, license fees for cabs and drivers, and an ample provision for incidental expenses.

It is assumed by the promoters that 360 cabs, or 90 per cent. of the entire equipment, would be in constant commission, and the earning "possibilities" are presented in tabulations on an ascending scale, "beginning with the lowest probable amount per day which each cab might earn."

These tabulations are as follows:

With gross earnings of $8 each, per day, 360 cabs earn, per year	$1,051,200	
Tire charge on this basis	$26,280	
All other expenses, including depreciation	448,560	
Chauffeurs' percentage (20%)	210,240	685,080
Available for dividends		$366,120 or 24%
With gross earnings of $10 each, per day. 360 cabs earn per year	$1,314,000	
All fixed charges and expenses	777,060	
Available for dividends		$536,940 or 35%
With gross earnings of $12 each, per day. 360 cabs earn per year	$1,576,800	
All fixed charges and expenses	842,760	
Available for dividends		$734,040 or 48%
With gross earnings of $16 each, per day. 360 cabs earn, per year	$2,102,400	
All fixed charges and expenses	974,160	
Available for dividends		$1,128,240 or 73%
With gross earnings of $20 each, per day. 360 cabs earn, per year	$2,628,000	
All fixed charges and expenses	1,105,560	
Available for dividends		$1,522,440 or 100%
With gross earnings of $27 each, per day. 360 cabs earn, per year	$3,547,800	
All fixed charges and expenses	1,302,660	
Available for dividends		$2,245,140 or 149%

The figures are given as being based upon actual earnings "not only of other companies now in operation, but upon an actual four months' test made during March, April, May and June, 1908, with ten cabs." Five year contracts at prominent stands are said to be all arranged for. A further field for the company's activity is promised in the commercial field, in the establishing of a motor delivery system for retail stores. It is explained that "the company has already been approached by, and can at any time make contracts with, several of the largest New York stores for the delivering of goods. This department will be very profitable and will be a part of the present company."

The manufacture of the motors and parts has been given to the New Departure Manufacturing Co., of Bristol, Conn., and the latter concern is already busy at work on them.

To Make Taxicabs at Geneva Plant.

With a clear view of the field, another taxicab manufacturing concern has entered the lists, its name being the Cleveland Auto Cab Co., of Cleveland and Geneva, Ohio. The company has been incorporated with $150,000 capital, under Ohio laws, and has purchased the plant formerly owned by the Geneva Automobile Co., where the Geneva steam cars were at one time made. While the factory will thus be in Geneva, the general offices will be located at No. 318 The Garfield Building, in Cleveland. Actual work on the taxicabs will commence before long.

The officers of the company include G. W. Alden, president; L. E. Wing, vice-president and treasurer; and W. C. Lytle, secretary. While New York capital is chiefly represented, some local capital is also interested and S. D. Wetmore, mayor of Geneva, is among the directors.

Lamp Committee Reports on Prices.

Buffalo was the scene of a further meeting of the lamp makers on Tuesday of this week. A special committee of the M. A. M., which was appointed at the last meeting and which consisted of George Yule, F. E. Castle and E. J. Edmunds, reported to the lamp making membership their recommendations on uniform discounts to apply to the manufacturing, jobbing and retail trade. The recommendations have not as yet been decided upon for general adoption, although action is expected to be taken in the not distant future.

Gets License Separate from Thomas.

The Chalmers-Detroit Motor Co., which hitherto has been operating under the license of the E. R. Thomas Motor Co., of Buffalo, of which it was a part, was admitted to membership in the Association of Licensed Automobile Manufacturers on July 17, thus becoming a recognized independent entity. According to a statement issued by the Licensed Association, it is expected that the "policy of strengthening and enlarging the Association is only begun" in the admittance of the Chalmers-Detroit Co.

Allen Crossing the Atlantic.

Walter Allen, who has obtained control of the import of the Mercedes, sailed this week for a brief European trip. His visit abroad largely relates to arrangements for the coming year.

The Jonz Automobile Co. has commenced operations in Beatrice, Neb. The factory is now at work on a number of cars for the coming season.

PRESIDENT DALE DIES SUDDENLY

Was Head of the Rubber Company Controlling Prominent Tire Concerns—His Rise and Career.

Charles H. Dale, president of the Rubber Goods Mfg. Co., died suddenly of heart disease at his summer home at Larchmont, N. Y., on Saturday morning last, at the age of 56 years. He has been ailing for several weeks, but a serious outcome was not anticipated, and the end came as a severe shock to his many friends.

Funeral services were held at Larchmont on Monday afternoon, and were attended by the executive officers of all the companies affiliated with the Rubber Goods Mfg. Co., and the directors of the United States Rubber Co. As a mark of respect, the different plants and branches of the Hartford Rubber Works, Morgan & Wright, and the G & J Tire Co. throughout the country, were closed during the entire day, and on Tuesday from 10.30 a. m. to 1 p. m., when the interment, which was private, took place.

In addition to being president of the Rubber Goods Mfg. Co., Mr. Dale was a director of the United States Rubber Co., the Merchants Exchange National Bank, and the Century Bank; and was a member of the Union League Club, New York Yacht Club, Larchmont Yacht Club, Automobile Club of America, and the New York Athletic Club.

In both business and private life Mr. Dale was an attractive personality, and was easily approached. He took more than a passing interest in the employes of the various companies under his control and placed implicit confidence in them. His associates revered and honored him as a man and friend, and many felt the influence of his disposition to help those around him.

His own career was an example of enterprise rising to success. After being graduated from the Cheshire Academy, Cheshire, Conn., he immediately started to carve out his own fortune. He went West and became interested in mining. About 30 years ago he went into the employ of the West Shore Railroad Co. and was in charge of the first passenger train over that line from New York City. After railroading for a number of years, he was attracted to the rubber trade and accepted a position with the Peerless Rubber Mfg. Co., taking charge of its railroad department. Finally, with several others, he purchased a controlling interest in the concern, which later was disposed of to the Rubber Goods Mfg. Co. Under his management as president, the Peerless company had become one of the largest and most profitable manufacturers of mechanical rubber goods in this country.

Succeeding Charles R. Flint, he became president of the Rubber Goods Mfg. Co., in this position becoming identified with the automobile and bicycle tire industries. He instigated the building of the new Morgan & Wright plant at Detroit, Mich., and practically reorganized all of the tire factories connected with the Rubber Goods Mfg. Co., these, in addition to Morgan & Wright, including the Hartford Rubber Works Co. and the G & J Tire Co.

Briscoe Entertains Maxwell Agents.

The branch managers of the Maxwell-Briscoe Motor Co. gathered at the main office in Tarrytown, N. Y., last week for their annual convention. Monday's program consisted of reports and discussions on business conditions throughout the country and an examination of the cars which constitute the offerings for the coming season. Tuesday was started with a "rubberneck" tour of New York City and in the evening Benjamin Briscoe gave the guests a banquet at the Cafe "Mar-tan," as the French proprietors insist "Martin" should be pronounced. After the banquet Briscoe disclosed part of a new automobile selling plan which is designed to be of great assistance to the agents.

Magneto Orders Crowd New Plant.

Magneto orders for the coming season are already testing the capacity of the new plant of the Remy Electric Co.'s plant, at Anderson, Ind. In addition to handling what is believed to be the largest single order for magnetos ever placed, that of the Buick Motor Co., the company has also on hand an order from the Overland Automobile Co., of Indianapolis, for 1,500 magnetos, together with several other large entire equipment orders.

Three Makers Join "Independents."

Two makers of buggyabouts, the Holsman Automobile Co., of Chicago, and the W. H. Kiblinger Co., of Auburn, Ind., have been added to the membership of the American Motor Car Manufacturers' Association. At the same time another member was likewise added, in the Midland Motor Co., of Moline, Ill., whose car is a product of the factory that formerly made the Deere-Clark.

Reeves Reappears at His Office.

Manager "Al" Reeves, of the American Motor Car Manufacturers Association, has so far recovered from his appendicitis operation as to appear at his office. A visit to Saratoga, N. Y., incidental to seeing the Glidden tour finish will break the force of his getting directly into harness again for serious business.

Butcher Takes Timken Territory.

H. E. Butcher, who until recently was at the head of H. E. Butcher & Co., manufacturers' agents at Detroit, Mich., has joined the forces of the Timken Roller Bearing Axle Co., of Canton, O. He will act as a traveling salesman for the company's products.

PERMITS TRANSFER OF POPE CASH

Connecticut Court Allows Receivers Money to Pay Creditors' Dividend—Reorganization is Expected Shortly.

Following the orders of the New Jersey court authorizing the receivers of the Pope Mfg. Co. to pay another or second dividend of 25 per cent. on all the approved claims, a hearing was held before Judge Howard J. Curtis in the superior court at Hartford, Conn., on Tuesday of this week on the motion to permit the receivers to transfer the necessary money to the control of the New Jersey court, in order that the payment may be made.

The lawyers for the receivers asked for permission to transfer $380,000. The receivers in Connecticut have $628,791.97 on hand, which together with all the money that they hold, a part of which will have to go to other jurisdictions, gives them a total of $1,378,000. Opposition was presented to the granting of the order for the transfer, but a compromise was finally reached whereby $300,000 is to be given over to the jurisdiction of the receivers in New Jersey.

Judge Curtis also passed an order giving the Connecticut receivers permission to carry on the business for four months from August 28. A complete reorganization of the company is expected to take place before that time, according to Arthur L. Shipman, one of the attorneys for the receivers.

Mitchell Agents' Midsummer Meet.

A "make merry" meeting of Mitchell agents at the factory in Racine, Wis., will be held August 27, 28 and 29, at which time the 1909 models will be shown and demonstrated. Agents from all parts of the country are expected and about 50 of the new cars will be ready for their inspection.

Have Stoddard-Dayton Date at Dayton.

Agents of the Stoddard-Dayton will foregather at Dayton, O., on July 29th, for a four days conclave at the factory of the Dayton Motor Car Co. The models for the coming season will be shown and the reasons for Stoddard-Dayton enthusiasm made clear.

Rapid Building a Big Addition.

Large additions to the factory of the Rapid Motor Vehicle Co., at Pontiac, Mich., have been started. A reinforced concrete building, 300 by 60 feet, is under way. This will make the sixth enlargement of the plant since it started three years ago.

The Michelin Tire Co.'s factory at Milltown, N. J., has for the last five months been running 24 hours a day. Present conditions indicate no relaxation in the necessity for night work.

The Great Efficiency Run

Introducing the Model B

BRUSH RUNABOUT

DETROIT TO
1—Boston via New York.
2—Washington via Pittsburg and Philadelphia.
3—Kansas City via Cincinnati and St. Louis.
4—Minneapolis via Indianapolis and Chicago.
5—Chicago and Return in Delivery Car.
COVERING 14 STATES

Anticipating a considerable increase in our production (now 8 to 10 per day), we will, on the appearance of our Model B car this week, send four runabouts and one delivery car over the above routes in order to show this wonderful little car to all sections. With the detours necessary to cover good towns and agency points, the first four routes will be over 1,500 miles each, and the fifth about 750. No particular speed is required, though with the stops for demonstrations it will be necessary to move lively to complete the run in two weeks.

A silver cup and cash prize will be given to the driver who uses the least gasolene and oil per mile, and a complete record will be kept by the observers of all repairs and adjustments.

Observers have been selected among newspaper men. They will carry keys to the tanks and otherwise be given facilities for accurate checking of the performance. At the end of the tours an illustrated booklet will be issued giving exact data.

In connection with the tour the good roads movement will be pushed and good roads literature distributed. The Michigan State Highway Commissioner, the Hon. Horatio Earle, a notable advocate of good roads, will assist us in this feature, and we expect similar help elsewhere.

Mr. Fred Nash, the famous cartoonist and writer, will have charge of the publicity end of the tour and illustrate it with humorous sketches.

Many people have asked us

Why We Do Not Run in the Glidden Tour

Simply because this run will do us more good for money expended, as we can stop and demonstrate; because it covers over 400 good towns in the bulk of the good buying territory; because while run under normal touring conditions it is a more severe test than the Glidden tour, as no attempt is made to find good roads; because it will give the average performance of five regular stock cars instead of one specially prepared; because more people will see it and have time to look at it and it will thus benefit more of our dealers than scurrying along in a cloud of dust with a hundred other cars.

Announcements of the progress of the run will appear in such issues of the trade papers as appear during its continuance, and daily bulletins will be mailed to a list of those interested. Write us if you wish to be on this list.

The Model B Brush Runabout is a wonderful car. Wonderful in efficiency, in economy, in durability, in convenience. The price remains the same, $500 with solid tires, $550 with pneumatics, and $600 for the delivery wagon.

NEW YORK, JULY 23, 1908.

A Question of Safety.

It is noteworthy that the main purpose of the improvements in motor car construction which are now taking place is in the line of increasing the durability and safety of the machine. The problem of producing a motor of adequate power to propel a car of given weight, or of designing a transmission to carry that power through to the driving wheels, no longer is a momentous task of itself. It is the production and adaptation of materials capable of resisting extraordinary conditions, and without the accumulation of excessive weight, which most concerns the designer at the present time. Yet in the movement for increased safety in motoring, which is the real intent of this effort, it is curious to reflect that in that most perilous danger center, the gasolene tank, the use of so soft and ductile a metal as copper still continues, with rare exceptions. That no more serious consequences attend its general use under a wide variety of conditions, is equally to be wondered at considering the arduousness of the duty thrown upon it.

Despite the effect of new methods of staying and suspending the fuel tanks, the fact remains that the number of collisions or smashes which are accompanied by the incidental destruction of the tank, is too great to pass without notice. Generally speaking, this incident is followed by the burning up of the wreck—a thing which might have been avoided were the fuel tank made of stronger metal and provided with an emergency valve to seal its contents automatically at such a time. In the case of tanks mounted in the rear of the car, and therefore open to the effects of the ever imminent rear-end colision, the danger of using thin and soft metal is increased. The enclosed tank, placed under the front seat, usually is protected except when the car is overturned or the forepart of the body is smashed. The rear, underhung tank, however, remains exposed at the risk of carelessly driven following vehicles, flying stones, and high obstructions in the center of the road.

That it is perfectly possible to use galvanized iron, or iron otherwise coated to guard against corrosion and the effects of the gasolene, as indeed is done in one or two instances, makes it appear all the more remarkable that the subject has not been given more serious attention by the makers hitherto. Obviously its cost should not act as a deterrent, nor the question of the added weight of the stronger tank. It is true that flanged couplings would be required in place of soldered-on connections, and that the method of fixture to the chassis would have to be such that no weaving or lost motion could occur in the tank. This ought not to be difficult to accomplish, however, and it is not easy to see why the matter has been permitted to pass without comment, for so long a time.

An Unsettled Controversy.

It is somewhat surprising to note the almost complete cessation of the "battle of the cylinders," in regard to the relative merits of combinations of fours and sixes, which at one time, not so long since, threatened to move the industry to its very depths. Contrary to what might have been expected from the preliminary skirmish, there are no present indications that the close of the year will see complete victory. There is every reason to suppose, in fact, that makers who now are devoting themselves exclusively, or to a large extent, to the production of sextuple engined machines, like those who have stuck to the quadruple type, will continue to build models of a similar nature. Furthermore, it appears that the question as to the relative merits of the two types is fast losing interest for the owners as a class.

It is pretty generally admitted that both parties to the controversy have been forced to make concessions during the interval since the six-cylinder motor came into a position of real comparative merit with the four cylinder type. The question as to which of the types is best suited to the work of propulsion, is now recognized as being not one of power, nor, in general of cost, but of comparative smoothness of operation, particularly when propelling the car at low or moderate speeds and on high gear. Matters of cost of production, maintenance and operation, have been found to equalize more closely than had been anticipated, when comparison is based on general uniformity of design and an equal power output. In consequence, it is reasonable to suppose that in his growing appreciation of actual running ability in the complete car, and his recognition of his own impotence in determining its specifications, the average owner is inclining toward a position in which he will leave all questions of pure design to the manufacturer.

On this supposition, the question is destined to continue to be rather more of commercial and technical interest to men in the trade and designers, than to the motoring public. Consequently it may be supposed that those makers who have "gone into" six cylinder construction after thorough experimentation on an original basis and have succeeded in producing motors which are without serious defect, will continue to produce them until such time as more complete developments in the art of gas engine design shall have revealed really striking points of advantage for one or the other of the two types. Similarly, those who have succeeded in developing four-cylinder motors which are not open to criticism at present, will probably adhere to their present policy. It is those makers who have placed themselves in the equivocal position of building two types of motor of practically equivalent power, but of the two sorts, who will feel the need of making a permanent decision in favor of one or the other, since economy of production demands the elimination from the product of all variety that it may be possible to

Digitized by Google

accomplish without reducing its scope.

It is observable that the double-opposed motor has been granted a regularly established status in cars of a certain class—light, economical, relatively small. That ultimately a similar classification embracing motors of medium power of the four-cylinder type, and of high power, of the six-cylinder type may come to be established, for good and sufficient reasons, would be a logical conclusion, more or less upheld by an apparent trend at the present time.

The Endorsement of the Trade.

Whether it be held as a matter of nice discrimination that the manufacturers of automobiles are not entitled to a hand in the control of what is purely the sport of automobile competition, or whether the opposite view be taken in the matter, the action of the National Association of Automobile Manufacturers in upholding the standard of the American Automobile Association in its governmental capacity cannot fail to have a clarifying effect on a situation which was in danger of becoming needlessly complicated. It may be assumed that the A. A. A. might have been able to establish proper relations with other recognized bodies abroad without any action from outside sources which might be construed as needless interference. At the same time, it is almost certain that the foreign associations, which are uniformly under the sway of trade influence, will be deeply impressed with the endorsement presented them, and that its effect will be to hasten a settlement of their present misunderstanding. Incidentally, the action serves to emphasize the untenable attitude of the Automobile Club of America, of New York, and serves as an interesting comment on the futility of its hope to attain the mastery of the automobilists of America.

Prospects of the Motor Stage.

That the motor stage is "making good" in various localities is a matter of no question, though its development has not been attended with the eminent success that at one time was predicted for it. In many localities, it has been found a more or less expensive luxury, though perhaps, not necessarily so. In others, particularly where long hauls are the rule, it has attained a prominence which speaks volumes for the certainty and despatch of its service. This is particularly true of instances of its use in the extreme West, where questions of operating cost, like those of tariffs, are subordinated to considerations of schedule. That it is destined ultimately to become of no small importance in feeder work, both within corporate limits and on the fringes of civilization, is an old conclusion which is fully endorsed by present experience.

The use of motor cars for commercial purposes has not progressed to such a degree that a proper conception of its business side has been developed. The enthusiastic promoter, however good his intentions, often lacks the knowledge and experience required for a fair handling of the equipment. This alone stands in the way of a successful employment of motor stages in many instances where, other things being equal, prospects are good for a profitable outlay of capital.

The rate at which enterprises of this nature are multiplying in the western States is really surprising. It speaks volumes for the faith which the performance of the pleasure car has inspired, and for the extension of business which is promised in the future. But that increased popularity, more especially in the line of passenger-carrying vehicles, can be brought about only by the exercise of proper discretion among the manufacturers and their agents, in placing machines under conditions where careful and rational treatment is assured to them, at least so far as this may be possible.

How to Develop Exports.

It is not a particularly inspiring outlook for the business of automobile exportation to Ceylon which is presented by American Consul E. A. Creevy, of Colombo. It is the old story. Roads are bad, hills steep, fuel costs high, and the possible buyers not yet alive to their needs in this respect. At the same time his message serves a useful purpose first, in showing that a definite opening for motor cars exists, and how the land lies, and second, because it points the way to successful exploitation. The principle of personal representation on the ground is one which has been shown to be desirable, if not absolutely necessary, in several other instances of a similar nature. Long-distance selling methods in which catalogues printed in a foreign language figure most conspicuously, and in which are shown no appreciation of local conditions, are not destined to be crowned with success. Whether the export trade is to be fostered throughout the field, in specially favorable localities only, or not at all—is for the makers to decide. The fact remains that the situation cannot be handled at arm's length, as has been proved in the case of the few concerns who are really advancing in this line.

COMING EVENTS

July 25, Philadelphia, Pa.—Norristown Automobile Club's race meet at Point Breeze track.

July 26-26, San Francisco, Cal.—Automobile Dealers' Association's reliability run to Del Monte.

July 29, Des Moines, Iowa—Iowa Automobile Club's race meet at Fair Grounds track.

Sept. 1, 2, 3, and 4, Chicago, Ill.—Chicago Motor Club's postponed 1,000-mile reliability run.

Sept. 7, Columbus, Ohio.—Columbus Automobile Club's race meet.

September 7, Lowell, Mass.—Lowell Automobile Club's road race at Pawtucketville, Mass.

November 26, Savannah, Ga.—Automobile Club of America's (New York), 400 miles outlaw race for foreign cars.

December 31-January 7, New York City—American Motor Car Manufacturers' Association's annual show in Grand Central Palace.

January 16-23, New York City—Association of Licensed Automobile Manufacturers' annual show in Madison Square Garden.

Value of a Legalized Monopoly.

No man can estimate the intrinsic value of the aggregate of patent holdings to the business world. Similarly it is impossible to estimate the amount of money which has been sunk in patents and to no purpose. But despite the great price which is paid for the exclusive right to use an invention or the product of an invention, it is an open question how much actual return is gained on patent investments, in the general sense. The cynical phrase, "a patent is merely a license for litigation," recurs with haunting persistency. A question even suggests itself at times as to whether it pays to recognize the validity of patents except when compelled to do so, or to seek protection in such a way, when its enforcement means, perhaps a greater loss than would be sustained at the hands of open and unfettered competition. The sophistry of the idea, however, is plainly revealed when it is considered what strange chaos would be produced to-day, were the patent laws suddenly nullified, and all their monopolies coincidently rendered void.

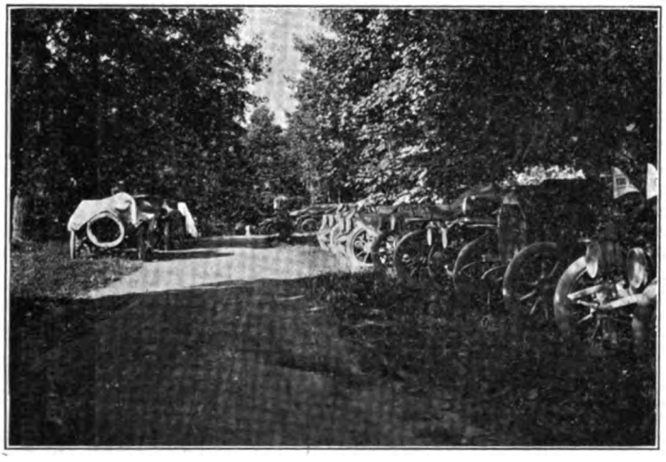
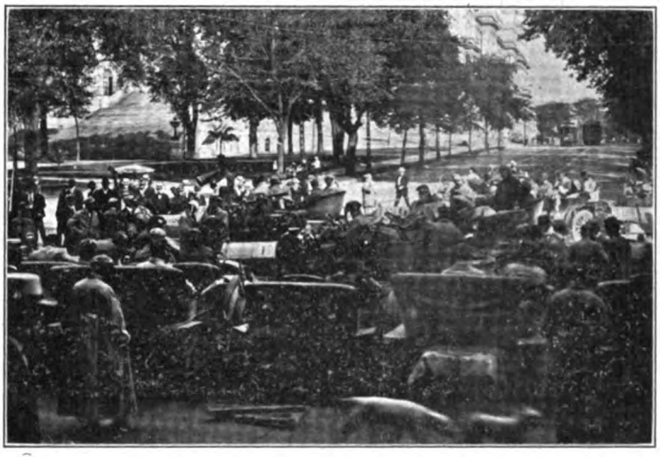
HOWER FAILS AS A BREAKER OF TIES

Glidden Tour Marked by Surprisingly Few Penalizations Despite Strenuous Route and Drastic Rulings—Three Teams Enter on Last Stage Unpenalized—Many Perfect Individual Scores—Of 46 Who Began the Long Journey Only 12 Dropped Out of the Running.



At the start of the last day's run, the three perfect score teams competing for the Glidden Trophy are the Pierce Team, of the Buffalo Club; the Peerless Team, of the Columbus Club; and the Chicago Team, consisting of two Haynes cars and an Oldsmobile.

In the Hower Trophy contest for runabouts the perfect score cars are the two Pierce Arrows, two Stoddard-Daytons, and a Premier.



The two Stevens-Duryeas, competing for certificates only, have perfect scores.

In addition to these cars there are 13 cars competing on penalized Glidden Tour teams that individually have perfect scores. The list includes the Rainier, the Oakland, two Studebakers, the Gaeth, the Thomas, two Franklins, the Reo, the Premier, two Marmons, and a Garford.

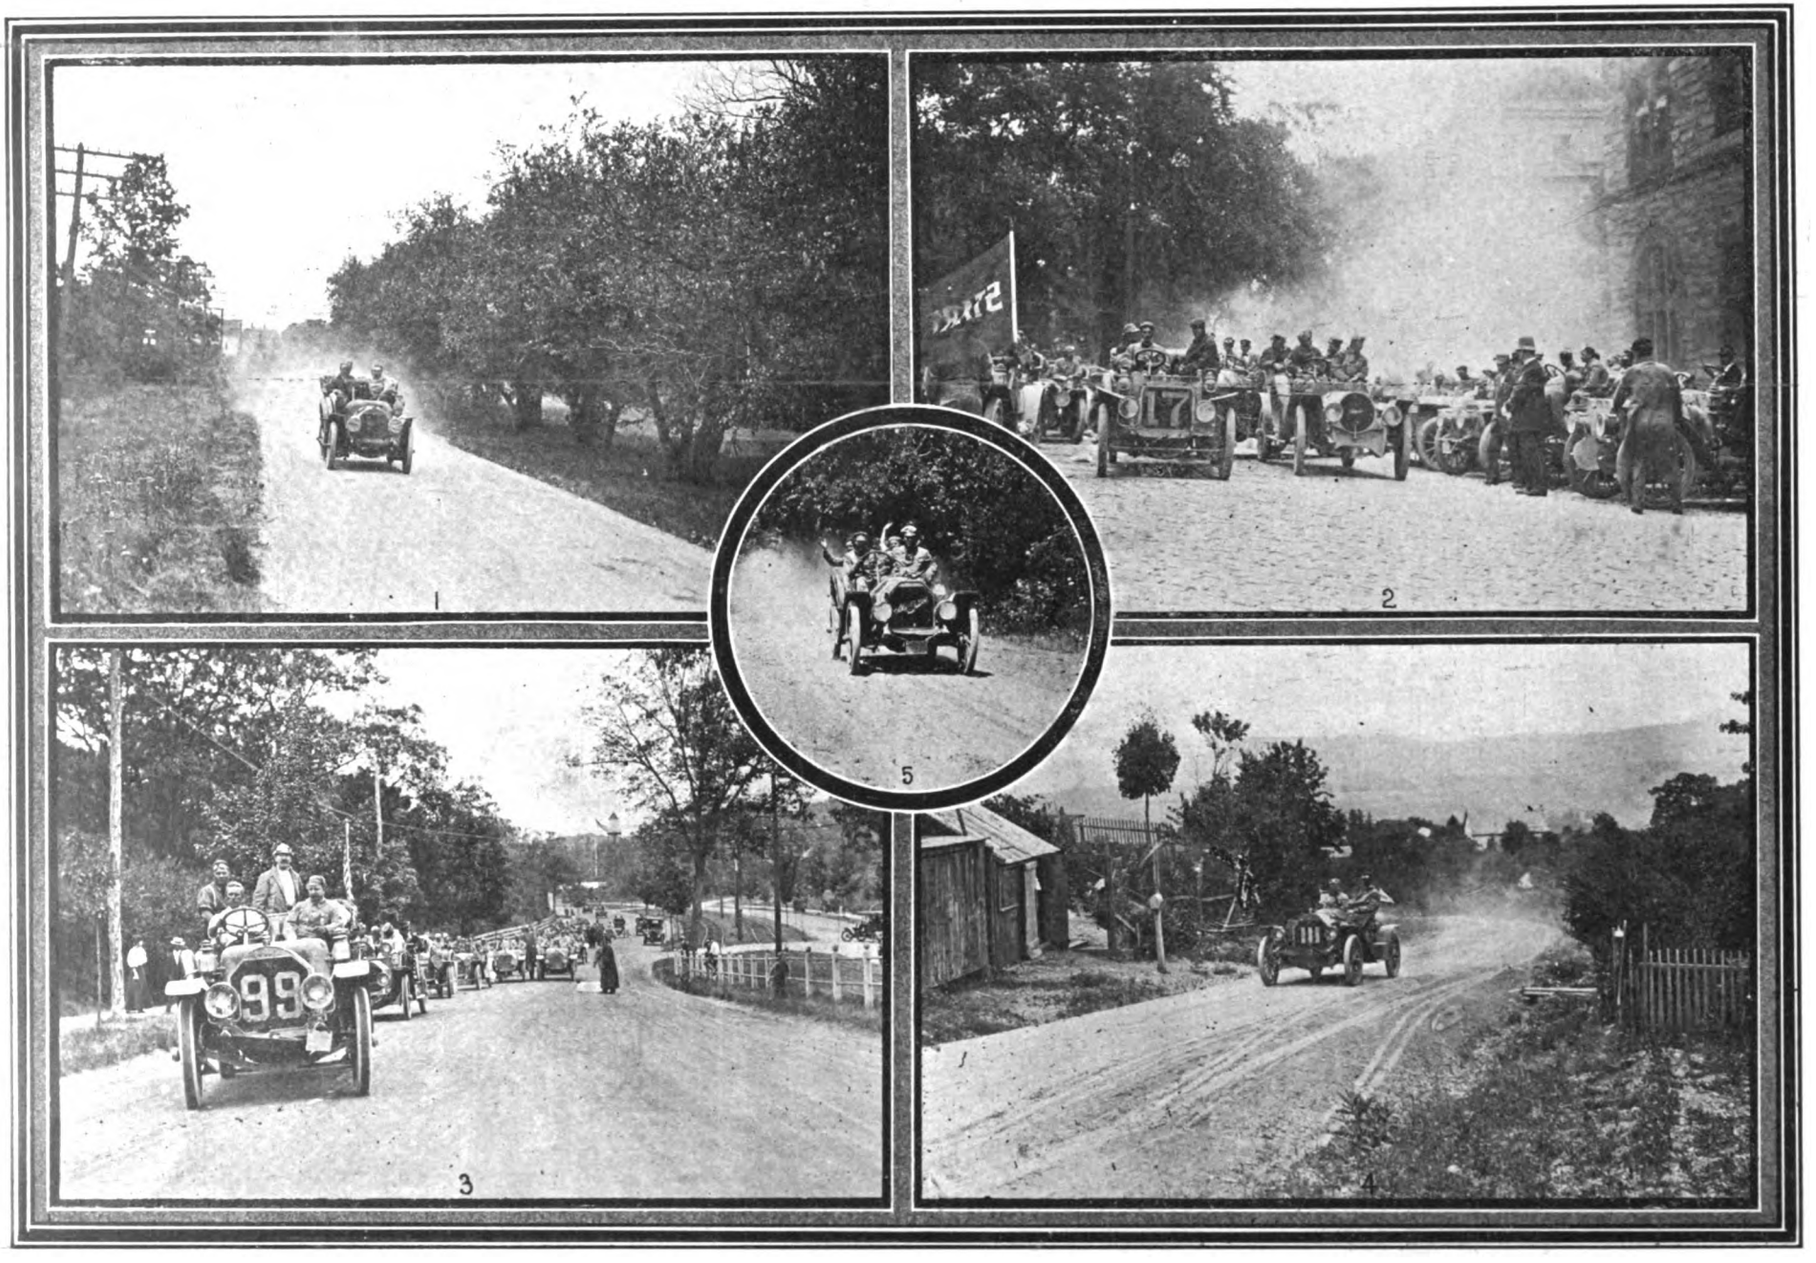
Of the total of 46 cars actually competing in the tour, 29 have come through to the last day with perfect scores, 12 have dropped out, and 5 continue to the finish with penalizations. The contest will be run until ties are broken.

IN BED AT MILFORD, PA.

RENDEZVOUS AT ALBANY, N. Y.

Except in a comparative sense, Philadelphia is not a Southern city, but being the southernmost point of the trip, the tourists were glad to leave it, on account of the hot weather, and head northward on Wednesday, July 15. The night stop was Milford, Pa., 132 miles away, and the plunge into the rolling upcountry and later into the mountainous district brought delightful relief in pure cool mountain air. None of the Glidden cars incurred any penalties, but two of the Hower contestants met with trouble, one of them being a perfect score car up to that point. This latter was the Reo, No. 101, driven by R. L. Lockwood, which lost 12 points for being late, making its remainder of points 665, as it had previously been penalized 302 points.

Accidents happened to the Premier confetti car and to the Gyroscope runabout, No. 113, which was continuing as a noncontestant. The Premier broke its front axle as the car was near Nazareth, 69 miles from Philadelphia and 6 miles from Easton. No harm was done the occupants. The Gyroscope precipitated a more exciting incident. As it was going about 25 miles an hour, its steering arm broke, and the machine darted off the roadway, down a steep embankment. It crashed into a huge log which lay crosswise of its path. The log was loath to take up movement too rapidly and retaliated by crushing in the whole front of the car. Both the driver and the mechanic had jumped, and they landed some 20 feet away in soft dirt. At this point it was decided that the Gyroscope would not continue the trip with the rest of the tourists. The scenery of the day was a pleasure to all who took the leisure to observe it. Especially around the Delaware Water Gap were splendid views unfolded to the eye, and the combination of mountain and water scenes gave pleasant variety.



From Milford to Albany, 158½ miles, was on Thursday made the basis of a 19 miles per hour schedule, the time allowed for the big cars being 8 hours and 15 minutes. This was ample, despite the fact that the actual distance was some 6 miles more because of a necessary detour. The smoothness of the roads and a cross wind which blew the dust away, made high speed possible without discomfort. The wind did not confine itself to blowing the dust, however, and removed considerable of the confetti trail, which at times bothered the drivers who were following it. The Catskills made the roads very winding in places, and many of the speedy cars found difficulty in keeping to the curves.

The Glidden Team No. 2, of the Buffalo Club, suffered as a result of steering knuckle trouble on the Premier driven by J. W. Moore. The car withdrew to make a satisfactory repair, the team being penalized 333⅓ points. No serious accidents marred the run, although Mrs. Cuneo had a near-smashup with a freight train, compelling quick use of the brakes, while the Gabried horn car followed wind-tossed confetti up an alley and dished a wheel.

Again the scenery features were strong, the Hudson River being in plain view from many points on the trip, and the Catskills themselves presenting very rugged and beautiful effects. These were lightened in places by flippant signs invented by occupants of the press car, bearing messages like "Suppose we should lose Hower," and a little further on, "What the thunder would

GLIMPSES OF THREE STATES ON ROUTE OF GLIDDEN TOUR.

1. On the Good Roads of Massachusetts. 2. On the Pavements of Albany, N. Y. 3. On One of Boston's Boulevards.
4. Approaching Milford, Pa. 5. Acknowledging Greetings.

Digitized by Google

we care," while at a placid lake the sign said, "Franklins take on water here," which caused the air-coolers as much amusement as anybody else.

ONE OF THE MARMONS AT ALBANY

After the first rush of rapid going, it was seen that there was plenty of time, and so a more moderate pace was maintained, giving opportunity to enjoy country. The pacemaking car lead a slow procession into Albany where the luxuries of the Ten Eyck hotel awaited the tourists. The Rapid truck had arrived early with the baggage, and there was a pleasant scramble for bathrooms and clean clothes.

Friday took the tourists 194 miles, the distance from Albany to Boston, and while it broke only one perfect score in the contest, it developed plenty of wayside trouble of one kind and another. The time allowed was 10 hours, which means "going some" in places. The first 90 miles was through the Berkshires to Springfield, Mass., where the Stevens-Duryea Co., the Fisk Tire Co., and the Knox Automobile Co. joined in serving a collation at the gasolene control, from the kitchens of the Hotel Worthy. There was no extra charge for "fruit taken from the table," and the tourists were grateful for the lunch even if they could not stop to take it in deliberate courses.

From Springfield on to Boston it was a dusty race through level country, and the speed regulations of many towns were ignored. After the time consumed in getting through the Berkshires and in making the descent of the famous Jacob's Ladder, it was thought necessary to "open up" in order to keep to the schedule. The usual speed traps in many places were not employed to annoy the tourists, a bit of courtesy which was much appreciated, but no enthusiasm or demonstrations of welcome and good will, such as were common on the other parts of the tour, were shown. In fact, the Massachusetts residents manifested a supreme indifference to the tour and hardly deigned even to look at the cars as they went by.

The smashing of a wheel on the Studebaker, No. 25, took 333⅓ points from the hitherto perfect score of the Rochester Automobile Club's Studebaker team, as the new wheel that was put on had not been inventoried in the original list of parts carried and therefore disqualified the car. In addition to considerable tire trouble, a number of minor repairs were found necessary among the other cars. The Haynes car, No. 19, broke a strut rod on the rear axle, but a new one was built from raw material and put in without the car incurring any penalty. The No. 16 Stevens-Duryea dismounted its leaking radiator, repaired it, put it on again and finished in good time without penalization. Similarly other cars were able to fix up minor difficulties without using spare parts and with no loss in points.

PICTURESQUE VIEW EN ROUTE

H. A. Van Tine, whose Garford, No. 29, broke a wheel on the run to Bedford Springs and was therefore continuing as a non-contestant, had a narrow escape from serious accident. Just after leaving Worcester he came upon a heavily loaded wagon as he was rounding a turn at high speed. He had to take to the ditch, and smashed into the fence. After missing a tree the machine turned around and stopped. A tire was torn off and the passengers were badly frightened, but matters were soon fixed right and the car resumed its journey. "Rough Rider" Hurlburt, in another Garford, knocked off his usual number of side-rails from the little bridges on the road and rocked the scenery generally, but met with no mishaps to his car beyond a few dents in the side.

The evils of throwing things at the tourists had a painful demonstration when James McLean, an observer riding in a Franklin, was struck in the eye by an apple which had been tossed to him by a young girl. The apple hit his goggles, the glass of which broke and cut him badly. His wounds were taken care of as well as possible by the other occupants of the car until Springfield was reached, when he was hurried to a doctor's office and two stitches were put in. He came unpleasantly near having his right eye destroyed, but by good fortune the glass had not penetrated the pupil. A mechanic in one of the Peerless cars was struck the day before by a pine cone thrown by a boy. He leaped from the car, caught the offender and gave him a not too gentle booting. The circumstances in McLean's case, however, were in many respects so different as to make this line of action hardly feasible.

TROUBLE ENCOUNTERED ON A ROUGH ROAD

No stop was made at Worcester and at Auburndale the contestants were met by

Digitized by Google

25 cars filled with members of the Bay State Automobile Association. For the entrance into Boston a procession was formed, in which the Marmon team, representing the Bay State Club, was given the place of honor. It was an imposing array that whirled into Boston and rounded up at the Hotel Somerset, at 4 o'clock in the afternoon. The spectacle of the dusty cars accompanied by the shining clean machines of the local automobilists and Milton Lusk doing the calliope act on his Gabriel pipe organ quite roused Boston's interest, as the city had never before seen a Glidden tour in the act of Gliddening. Bouquets were presented to the ladies, and after the travelers had had a chance to wash up, there were speeches of welcome and other pleasant ceremonies. Mayor Hibbard figuratively presented them with the keys of the city, and J. F. Hovstadt, of the local club, outlined the plans that had been for their entertainment.

Saturday and Sunday were spent in the luxury of late sleep in the morning, and clambakes and other festivities in the afternoon. What with special chartered steamers and other thoughtful arrangements, the Western visitors enjoyed the pleasures of the beach resorts and the harbor, while others toured the city, visiting points of historic interest. The change in personal appearance, when for a brief time at least the tourists could assume "purple and fine linen," was in many respects remarkable.

Monday morning's start from Boston had a distinct atmosphere of its own—in the psychological sense rather than in reference to the belching oil smoke. There was a feeling that the last leg of the tour was being begun and that if decisive events were to happen they would happen soon. Poland Springs, Me., 164 miles, was the first objective point, but the roads were so good and the weather so pleasant that not a score was marred or a penalty imposed. There was plenty of tire trouble, but all repairs and replacements were made with little delay.

The nearest thing to an accident that occurred was the falling of a bicyclist in front of a Pierce car, which swerved in time to save him, and an adventure which No. 14 Franklin had in avoiding a head-on collision with a reckless youngster driving a powerful and self-willed runabout. The driver of the Franklin, M. S. Bates, yanked his car to one side, where it almost went down an embankment into a pond.

From Poland Spring to Rangeley Lake on Tuesday, 141 miles, was more to Chairman Hower's liking, in that it spoiled another perfect score and lessened the number of teams in the tie. Not that Hower had any particular preference as to the teams he wanted to suffer, but he disliked the prospect of having cars going around the course all summer trying to run off their ties for the trophies. The Marmon team was the unfortunate one, No. 22, driven by C. L. Clarke, having trouble with the brake band. The car was penalized 10 points for tardiness. The Marmon interests protested strongly, on the ground that the car had been following the pacemaker, who was 15 minutes behind his schedule, but would not let the Marmon pass. It was claimed that had the pacemaker been up to schedule, the Marmon would have had ample time to fix its difficulties and get in on time, as it was only 10 minutes late. No decision was made on the protest, the 3⅓ points against the Marmon team being left standing. The Oakland, No. 28, broke its left front spring, and was 42 minutes late, thus getting a corresponding number of points penalty. This further reduced the Rainier-Oakland mixed team of the Chicago club to 983⅓ points.

By smashing a rear wheel in a deep hole on Wednesday, the Marmon car, No. 22, the justice of whose penalization the day before had been disputed, solved the whole difficulty, as it was obliged to withdraw, leaving the Bay State team with a score of 666⅔. The day's run from Rangeley to Bethlehem, N. H., in the White Mountains, was only 130 miles, but it was rough country and rain had made the roads slippery. Chairman Hower and Charles Glidden were pitched bodily out of their car at one point, when the machine was run to one side of the road to let a horse pass. The soft dirt of the road gave way and the car rolled over into the ditch. Hower was thrown beyond the ditch, down an embankment, where he made a rapid descent of 18 feet into a huckleberry bush. In the excitement of righting the car he was temporarily forgotten, but was later helped up to the road again somewhat dazed. The Oakland, No. 28, of the Chicago team, was again penalized, to the extent of 9 points, bringing 3 points against the team. A number of other cars met with difficulties, but in the case of the contestants they were able to make their repairs and get in on time, while the non-contestants were not subject to penalty for their delays.

PREMIER "CENTURY A DAY" PRESS CAR

F. B. HOWER (AT WHEEL) AND C. J. GLIDDEN

Rather than to spoil perfect scores, several of the cars are running without making replacements of lost or broken parts such as would ordinarily be made, as in the case of missing starting cranks or oiler connections. Studebaker, No. 25, took a try at breaking up a bridge and was partially successful. The bridge lost a good part of its side railing, while the car only lost a tire.

In the evening at Bethlehem a meeting of the contestants was held and it was arranged that the cars should parade into Saratoga in the numerical order in which they checked out from Buffalo at the start of the tour. This arrangement was designed to prevent racing for first arrival at Saratoga. It was also decided to let the contestants check out at 6 o'clock on the following morning instead of 7 o'clock.

Plans for a 1908 Glidden and Hower tour to Denver, with tenting parties en route, and a 1910 tour in England, Scotland and Wales, doing the 2,000 miles from Land's End to John O'Groat's, are already being discussed by the participants in this year's tour.

CHRISTIE GETS OLDFIELD'S SCALP

Sensational Struggle for First Place in Star Event at St. Paul—De Palma Wins Two of the Races.

With ideal weather conditions, the best field of entries ever gotten together in the West, a great throng of 20,000 people massed in the huge stands, no bothersome delays, fast times and not a mishap of the slightest character, together made the race meet of the St. Paul Automobile Club at the State fair grounds on Wednesday of last week, 15th inst., one of the greatest sporting events that ever has been held in the region of the Twin Cities.

CROWD OF 20,000 AT ST. PAUL MEET

The meet was held in honor of the visiting Shriners who are on a pilgrimage to St. Paul and camel drivers and the horsemen of the plains gathered in large numbers to watch the modern leviathians vie with each other in tests of speed. The scene presented by the assembled tribesmen and dwellers of the Twin Cities at the trackside was fascinating. On every hand gleamed the red, and yellow and the white of the fez of the Moslem faith, plotted in solid rows in the stands, scattered over the home course, sprinkled everywhere, while the tribal ribbons and silken emblems of the faith unfolded in the breeze in confused masses. The speeding machines flashed in lightning kaleidoscopic vision the red, the green and the yellow of the prophet. From the stands, packed in unyielding lines of congested humanity, the overflow flattened down into the paddock, spreading out on either side until the green of the grass was hidden. Truly it was a great and picturesque throng.

Naturally the most interest centered in the event known as the quadrangular sweepstakes for professionals at five miles. Kilpatrick's big racing Hotchkiss did not arrive in time for the start, but it did not make much difference with the crowd as they had conceded the event to either Christie or Oldfield. Ralph De Palma, who by the way, in this event drove Oldfield's discarded Green Dragon, was the third starter. Oldfield and De Palma went in the first heat, but the former was never headed. The Green Dragon exhibited signs of old age and was satisfied to quit after eating the dust for several miles. The final heat possessed more than ordinary interest as it brought together Christie and Oldfield. It may be remembered that last fall Oldfield arranged a $500 race at Pittsburg, not expecting any one with a car faster than his to appear on the scene. Christie unexpectedly appeared, much to Oldfield's chagrin, but he never had a chance for the $500, as he smashed up his car and landed himself in the hospital while making an exhibition run before the races. There was no hippodroming in this later race between Christie and Oldfield, as the former was after the champion's scalp, and how he got it is now a matter of history.

Oldfield drew the pole for a rolling start, but Christie jumped into the lead at the quarter and kept 20 feet of daylight between him and his rival until the three-quarters pole, when Oldfield slightly advanced his position and brought his front wheels even with the rear wheels of his rival. The succeeding miles were exciting. Oldfield would gain a little on the stretches, but Christie gained on the turns and it was nip and tuck until the last stretch, when Oldfield came tearing down the track, gaining on Christie with every second. That was when the crowd rose en masse and cheered, for each driver had his rooters. It was an exciting moment when Oldfield gradually closed the gap, but the tape was too far away and Christie flashed over a winner by ten feet. The time for the heat was five minutes flat.

The 25 miles endurance race proved more interesting than was expected, and but for an unfortunate occurrence it would have been the best event of the day. Soules in a Stearns, Schoenick in a Renault, De Palma in the Allen-Kingston, and Patterson in a Packard, were the starters. Soules and De Palma soon lapped the others. De Palma took the lead at the start and held it until the sixth mile, when Soules got a notion that he would like to kick up some dust. The position did not last for long, however, as De Palma again went up front and in the tenth mile Soules lost his goggles. The dust raised by De Palma's car was too much for Soules and he had to stop for his eye protectors. This delay was sufficient for De Palma to gain a lap and although Soules re-entered and kept hugging him to the finish, he never could regain the lost lap. Patterson and the driver of the foreign car both dropped out.

In the mile trials Christie, Oldfield and De Palma tried to reduce Christie's record for the track of 52 seconds. Christie failed by 2⅘ seconds, while Oldfield's time for the circuit was 56⅘ seconds. De Palma was clocked in 58 flat.

For the third successive time Oliver Crosby's Packard car won the Twin City championship race for stock chassis, Smith's Packard of Minneapolis, being the other contender. Patterson handled the St. Paul car and was never headed from the starting gun, winning ultimately by a quarter of a mile in five. The prize was the Twin City cup, with a gold watch fob to the driver.

De Palma had things his own way in the five miles event for 40 horsepower stock chassis, his Allen-Kingston winning over Patterson in 5:14⅘. Martin, in a Thomas, was third. The five miles event for cars costing $1,250 and less went to Charles Nyquist, Buick, in 6:05⅕.

Big fields and keen competition made the motorcycle events of more than ordinary interest, more than a score of riders starting in each event. The five miles handicap for machines not exceeding 30½ cubic inches piston displacement went to O. Gudenschwager, Indian, in 7:18⅘. Charles Van Sickle, who started from scratch, put up a beautiful race, passing man after man. He was beaten at the finish by only a length.

The ten miles open for motorcycles was won by F. S. Haas. The contest after the fifth mile resulted in a battle between Haas and Van Sickle, the former finally winning. The time was 11:22⅖. Van Sickle tried to break the mile track record but the best he could do was a lap in 1:01. The summaries:

Five miles for motorcycles—Won by O. Gudenschwager, Indian; second, Charles Van Sickle, Indian. Time, 7:18⅘.

Ten miles for motorcycles—Won by F. S. Haas, Indian; second, Charles Van Sickle, Indian; third, O. Godenschwager, Indian. Time, 11:22⅖.

Five miles for stripped stock cars costing $1,250 or less—Won by Charles Nyquist, Buick; second, Wheeler, Ford; third, Reynolds, Buick. Time, 6:05⅕.

Five miles for stock chassis, 60 horsepower and under—Won by Ralph De Palma, Allen-Kingston; second, Charles Soules, Stearns; third, Schoenick, Renault. Time, 4:58.

Five miles for stock chassis, 40 horsepower and under—Won by Ralph De Palma,

Digitized by Google

Allen-Kingston; second, A. H. Patterson, Packard; third, Martin, Thomas. Time, 5:14⅗.

One mile time trials—Won by Walter Christie, time, 0:54⅘; second, Barney Oldfield, Stearns, time, 0:56⅘; third, Ralph De Palma, Green Dragon, time 0:58.

Five miles Twin City championship for stock chassis—Won by A. H. Patterson, Packard; second, Bagley, Packard. Time, 5:23⅗.

Five miles quadrangular sweepstakes—First heat won by Barney Oldfield, Stearns; second, Ralph De Palma, Green Dragon. Time, 5:05⅘. Second and final heat won by Walter Christie, Christie; second Oldfield. Time, 5:00.

Twenty-five miles endurance derby for stock chassis—Won by Ralph De Palma, Allen-Kingston; second, Soules, Stearns. Time, 26:11⅗.

One mile motorcycle exhibition—By Charles Van Sickle, Indian. Time, 1:01.

Brush Plans Demonstration Tour.

Radiating from the Detroit factory in different directions, four runabouts and a delivery car of the Brush Runabout Co. will shortly set out on tours which in total will cover 14 States, 400 towns and cities, and some 4,000 miles, and which will have a triple purpose. Each car will carry an observer who will keep a record of the amount of oil and fuel consumed, as well as a detailed account of all repairs and replacements. A silver cup and a cash prize will be given the driver making the best showing in cost per mile.

The objects of the tour will be to show the cars in the principal towns and agency points en route, to get a record of performance, and to distribute good roads literature. Each car has a different route and objective point, the first going from Detroit to Boston via New York; the second to Washington via Pittsburg and Philadelphia; the third to Kansas City via Cincinnati and St. Louis; the fourth to Minneapolis via Indianapolis and Chicago; and the delivery car from Detroit to Chicago and return.

The observers will be newspaper men, among whom will be a cartoonist, so that there will be no lack of record as to what happens. The State highway commissioner of Michigan is going to help out with the good roads literature which will be distributed, and the agents and populace along the highway will be given every opportunity to examine the new models of the cars.

"Accelerative Test" the Latest Competition.

Among the forthcoming competitions on the calendar of the Royal Automobile Club of Great Britain, is an "acceleration test," which is to come off some time during August. It is intended to demonstrate the accelerative powers of the cars—as the name implies—with particular regard to their fitness for service under heavy traffic conditions, where quick starts and stops are an absolute necessity.

N. A. A. M. STANDS WITH A. A. A.

Makers Vote Exclusive Recognition of the Association as Governing in Racing—Foreign Bodies to be Notified.

The car makers belonging to the National Association of Automobile Manufacturers have taken a hand in making it clear that the American AutomobileAssociation is the governing body in racing matters in the United States. At a meeting of the executive committee on Wednesday of last week it was decided to advise the recognized clubs of Europe that the manufacturers regard and will recognize only the American Automobile Association as the governing body and that they will support only such events as are organized or sanctioned by the A. A. A.

The attention of the foreign clubs and manufacturers will also be directed to the fact that participation in events on this side that are not sanctioned by the A. A. A. will disbar the participants from the sanctioned events such as the Vanderbilt cup race and minor races and from all events to be conducted on the Long Island Motor Parkway.

Further resolutions were adopted approving the action of the central conference committee of the A. A. A. at Buffalo the day before in deciding that it would not be fair or just to change the rules for the Vanderbilt cup contest this year.

The representative character of the meeting was indicated by the presence of Thomas Henderson, of the Winton Motor Carriage Co.; S. T. Davis, Jr., of the Locomobile Co. of America; G. W. Bennett, of the White Co.; Charles Clifton, of the George N. Pierce Co.; Wm. E. Metzger, Northern Motor Car Co.; S. D. Waldon, of the Packard Motor Car Co.; W. R. Innis, of the Studebaker Bros. Mfg. Co.; C. C. Hildebrand, of the Stevens-Duryea Co.; L. H. Kittridge, of the Peerless Motor Car Co.; W. M. Lewis, of the Mitchell Motor Car Co.; R. D. Chapin, of theChalmers-Detroit Motor Co., and S. A. Miles, general manager of the association.

A proposition for a New York to San Francisco automobile race for general trade participation was considered at the same meeting, but it was decided that such a contest is at the present time unnecessary. The sanction for it has not yet been granted, and will be withheld lacking the approval of the manufacturers.

Chicago Wants the Thompson Cup Race.

Having renewed its allegiance to the American Automobile Association, the Chicago Automobile Club has evinced a desire to secure the management of the proposed stock car road race for the Jefferson De Mont Thompson cup. Sydney S. Gorham, secretary of the club, this week telegraphed Chairman Thompson of the American Automobile Association racing board, and donor of the trophy, expressing the club's wish to secure the race for Chicago and its vicinity. A course embracing a 22-mile circuit, without grade crossings, and running through only two towns, that is to say, Lowell and Crown Point, has been picked out with this event in mind, and is said to be admirably suited to the test. President Hotchkiss, of the A. A. A., was consulted with regard to the proposal during a recent visit to Chicago, it is explained, and his attitude is supposed to be favorable toward it. A petition to the governor of Indiana seeking his permission for the use of State troops to guard the course, already is being prepared for circulation in Lowell.

Point Breeze Meet May Cause Trouble.

Trouble is brewing in Philadelphia over a race meet that is scheduled for the Point Breeze track, Saturday, 25th inst. The Quaker City Motor Club has been planning to hold a race meet in Philadelphia about August 15th, thinking it not advisable to promote one at an earlier date. They were, therefore surprised to learn that a meet had been sanctioned by the American Automobile Association. Investigation developed that the sanction had been granted to the Norristown (Pa.) Automobile Club. The Quaker motorists resented very much the invasion of its territory by the Norristown club, and protested to the American Automobile Association with the result that the A. A. A. recalled the sanction granted to the Norristown club.

Despite this fact, the promoters of the meet decided to run it just the same, but altered their original plan of having a number of events. They now propose to run a 100-mile match race. J. W. Parker, Jr., a Philadelphian, is said to have agreed to meet any driver in such a race. The promoters tried to secure Wallace H. Owen, and failing to get him, made overtures to Louis Strang.

Graves Buys the Grand Prix Winner.

Extra spice will be added to the promised race for the Vanderbilt cup by the presence of the Mercedes, with which Leutenschlager won the Grand Prix race in France on the 7th inst. It is announced that his car has been bought by Robert Graves, who went abroad principally to see the great race, and who had intended to enter for the Vanderbilt cup race this year the Mercedes car with which he tried for the American trophy several years ago. Mr. Graves, it is said, will not be the only one to enter a foreign car in the coming race, as several other Americans are reported to contemplate the purchase of foreign cars and to compete with them on the Long Island course.

MONOPOLISTIC PHASE OF PATENTS

What They are and the Rights They Confer—How They Benefit Both the Inventor and the Public.

It is a remarkable fact that one of the most advantageous as well as one of the most abused of American institutions, should be a direct supporter of the monopoly, and as such, should receive the cordial endorsement of the public at large, as well as those who seek its specific protection. Patent law regarded and upheld as a monopoly probably is a novel idea to many who have not studied its logical effect very closely. As such, however, it has a legitimate basis, and is the natural outcome of the primitive method of protecting an original process or other invention by the crude device of secrecy. An unusually clear presentation of the structure of patent law, showing its origin as well as its rightful monopolistic purpose, is set forth in a paper read before the New England Society of Orange, N. J., recently, by Edwin J. Prindle, as published by American Industries. Its analytical view of the patent situation should be of considerable assistance in the establishment of a proper appreciation of questions pertaining to its use and abuse.

That the patent is a true monopoly is brought out by the following quotation from a recent decision, which the author introduces:

"Within his domain, the patentee is czar. The people must take the invention on the terms he dictates or let it alone for 17 years. This is a necessity from the nature of the grant. Cries of restraint of trade and impairment of the freedom of sales are unavailing, because for the promotion of the useful arts, the constitution and statutes authorized this very monopoly."

"The operation of the patent laws, like that of the laws of nature, is so unobtrusive that comparatively few realize their importance," continues Mr. Prindle. "They have been one of the most important factors in the development of our country from non-manufacturing colonies to the greatest of manufacturing countries. . . . .

"Before patents were granted for inventions, the inventor had but one way to secure a return from his invention. That was to keep it secret.

"Secret inventions were the most valuable possessions of many families and guilds. But in proportion to their value, they tempted the cupidity of competitors. The secret of making Venetian glass was greatly prized and was most jealously guarded. A Venetian named Paoli, who possessed the secret, left Venice and wandered northward practising his art. He was stabbed in Normandy with a dagger marked 'Traitor'—a measure taken to preserve the secret.

"In 1710 the Elector of Saxony learned that a man named Bottger had discovered the secret of making porcelain. He accordingly confined him in the castle of Albrechtsburg until the discovery had been perfected. The workmen were sworn to secrecy, and the draw-bridge was kept up except to admit those specially authorized. Thus was the manufacture of the famous Dresden ware begun. The secret was soon carried to Vienna, where a royal factory was established, and to France, where it was the foundation of the manufacture of the famous Sevres pottery. . . . .

"The inventor could only keep his invention secret where the invention was either a process of making something, or a machine whose product he could sell. If his invention was a new article of manufacture, or a machine, which was itself the subject of sale, the moment he sold one his competitor could see its construction and copy it, and that without the handicap of the usually costly experiments of the inventor in making his invention. There was, therefore, little encouragement to make any invention which could not be kept secret. This worked to the disadvantage of the public in several ways. First, the precautions to preserve secrecy necessitated a limited output by a single establishment, and resulted in a restricted supply at a relatively high price. Second, the secret if successfully kept, might and sometimes did die with the inventor, and so was completely lost to the public, or perhaps but an imperfect knowledge of it became public. Some of these lost arts have never been rediscovered. Third, the frequent theft of inventive secrets discouraged the production of inventions.

"The perfection of an invention often involves the expenditure of a large sum of money and a vast deal of time. As a not unusual example, I may state that a comparatively simple, special typewriter of not very large commercial possibilities cost over $200,000 in experiments and special machinery before it was ready for the market. If a competitor had been at liberty to copy the machine as soon as it was put on the market, the competitor would have been a large part of this sum better off than the inventor at the start. These difficulties greatly discouraged invention, and the public was deprived of many inventions it might otherwise have had.

"Thus the wisdom of granting the inventor an absolute monopoly of his invention for a limited term will be apparent. The inventor is encouraged to invent by the assurance that his exclusive possession of the invention will be preserved just as fully and much more certainly than if he kept it secret. The public is made certain of the possession of the invention at the end of the term by the requirement that in order to have a valid patent the inventor must fully disclose his invention at the time it is granted. . . . .

This, then is the nature of a patent: It is a contract between the public and the inventor, by which, in consideration of such a full disclosure of the invention that any person skilled in the art to which the invention relates can make and use it, the public grants to the inventor the right to exclude all others from making, using and selling the invention for a limited term (in this country 17 years).

"There are four classes of inventions which can be patented. These are arts, machines, articles of manufacture and compositions of matter. An art is an operation or series of operations performed by rule to produce a physical result. Thus the art of casting car wheels was patented, which consists of pouring metal into the mould in a tangential direction so that the metal acquires a whirling motion and the heavy solid metal is thrown out to the rim of the wheel and the light dross displaced toward the center. This gave wheels having tires formed of solid, durable metal.

"The class of machines needs no explanation. An article of manufacture is anything made by the hand of man that is not a machine or a composition of matter, such as a lead pencil. A composition of matter is any mechanical or chemical mixture of two or more substances, such as soap or a tool steel.

"The monopoly granted by a patent is a peculiar one. It is negative in character. It gives the right to exclude all others from making, using or selling of the invention; but it does not grant the positive right to the inventor himself to make, use and sell his invention, if he does not already possess that right. That is, if he cannot practise his invention without using that which has already been patented to another, then, while his patent gives him the right to exclude all others from his invention, he cannot himself make, use or sell any embodiment of his invention until the patent which he would infringe by so doing is dead. For instance, Bell invented the first speaking telephone, and Edison, Blake, Berliner and others invented telephones which were much more efficient than Bell's, and yet, although each of these later inventors received a patent for his improvement, he could not make, use, or sell his telephone without Bell's consent, because all of the later forms of telephone employed the principle that had been patented to Bell, although in an improved manner. A man cannot use another's invention merely by improving it.

"It is clear from what has been said that a patent must contain a description of the invention so full and clear that any one skilled in the art to which it pertains can practise the invention. In addition to the written description there are drawings, when the invention is capable of such illustration.

"Every invention is, however, an evolution (consciously or unconsciously) of some prototype, and therefore it is never true that the whole device which is represented

Digitized by Google

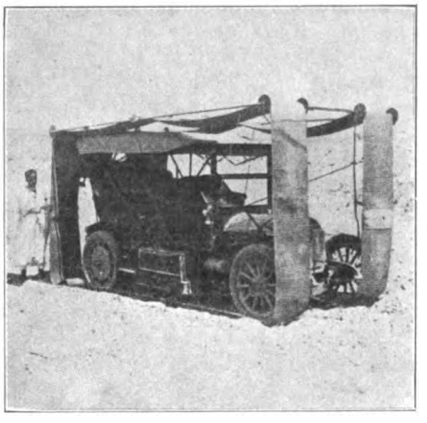
in the drawings is the conception of the patentee.

"How, then, is the public to know the limits of the patentee's monopoly, so that it may know what the public is free to make, use and sell, and what it must let alone? At first there was no way by which it could be told from the patent itself, and the monopoly included the entire machine, minus all the defendant in suit could prove to be old. Then the expedient was adopted of requiring the patentee to specify the part or combination of elements to which the improvement related, this being done in a clause or clauses at the end of the description, called 'claims.' These claims constitute the measure of the monopoly. For instance, the man who first invented the safety bicycle might have made such a claim as this:

"'I claim a velocipede consisting of front and rear wheels, a forked head having said front wheel pivoted in its fork, and having a steering handle at its upper end, a trussed frame pivoted on said head and having a rear fork in which said rear wheel is pivoted, a saddle on said frame, a crank shaft journaled in a bearing on said frame, a sprocket gear on said crank shaft and one on said rear wheel, and a sprocket chain connecting said gears for driving said rear wheel by the motion of the cranks.'

"From this the public would know the patentee did not claim that his invention included the high bicycle consisting of a large front wheel as tall as a man and having a small rear wheel, a perpendicular forked steering head, and a backbone pivoted to the head and having the small wheel mounted in a fork on the lower end of the backbone, the saddle being on the backbone up over the front wheel.

"They could be certain the latter form of bicycle was not within the monopoly granted, because, for instance, the claim includes as elements, the crank shaft, the sprocket gears, and the sprocket chain, by which the rear wheel is driven from the crank shaft. None of these elements is found in the old high wheel bicycle, nor are there any parts which perform the same function."



Attaching Speedometer Driving Gears.

In attaching the driving gear of a speedometer to the wheel, a simple method of centering it so that it is true in its relationship to the shaft gear, is to hold a piece of chalk between the fingers, and with the hand resting on and steadied by some permanent fixture, such as the steering arm, turn the wheel so that the chalk will mark the spokes of the wheel in a practically perfect circle. With this chalk outline as a guide it is easy to properly adjust the driving gear. Unless the gear runs true, it will be the cause of an objectionable noise and this annoyance will be avoided if care is taken when the attachment is put on the wheel. Naturally the life and usefulness of the speedometer depends to a great extent on the proper adjustment of the drive.

CARRYING ITS OWN ROAD ALONG

Odd Equipment of Car for Desert Travel—How a French Tourist Drove from Tunis to Algeria.

Long-distance tourists who depart from the better traveled paths of civilization with their automobiles frequently encounter serious difficulties in adapting themselves to the conditions of the trails which correspond to highways elsewhere. Bridge-building, swamp paving and general reconstruction work are merely incidents to such exploits. But it is seldom the motorist is obliged to carry his entire road along with him. This, however, was found to be necessary in the literal sense in connection with a journey in Southern Tunis and Algeria, which was taken not long since by a French motorist, M. G. Liegeard.

CAR EQUIPPED FOR THE DESERT

His 28 horsepower car with its equipment complete, weighed about two tons, which, with the ordinary tire equipment, would have been sufficient to sink the machine hopelessly in the sand of the desert, unless some special provision were made against it. After mature deliberation a scheme was settled upon which followed closely the idea of the designer of the curious "Caterpillar" tractor at present in use by the British War Office. That is to say, an endless traveling roadway was provided, which the machine automatically picked up and set down again, thus providing a uniform surface for the wheels to run upon.

The principle of the thing is shown by the accompanying picture, which is sufficiently suggestive in itself. Upon each side of the car a framework was rigged carrying rollers, over which were stretched endless bands of cocoanut fibre, some 19 inches wide, which passed along the ground under the wheels, and back overhead to the front again. The wide tread surface thus obtained proved sufficient to prevent the wheels from sinking into the sand to an excessive degree, and also protected the tires from the effect of thorns. In proof of this it is only necessary to indicate that although the desert section of the journey was more than 600 kilometers long, or about 375 miles, no tire troubles were encountered.

How to Treat Imitation Leather Tops.

"It is surprising to see wrinkles in some of the imitation leather tops, considering how easily this difficulty can be remedied," says the Carriage Monthly. "The fault is not at all with the imitation leather, but with the trimmer himself. In the first place it is misleading to suppose that an imitation leather top should be treated in the same way as it is customary to treat a leather top, and especially the drawing of the material over the naked bows, allowing a certain fulness for the curve.

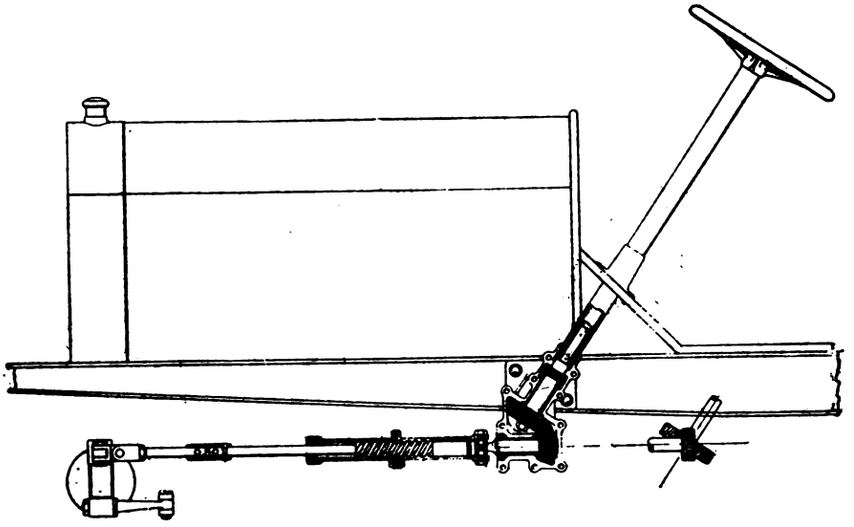
"A very good suggestion is to first cut the imitation leather in size to suit the center top piece and side quarters respectively. Next take the side quarters and paste the bottom edge, which, however, should be cut with a curve, about ½ inch, and if the top is long, ⅝ inch curve should be given. When tacking out to dry, see that the bottom edge is tacked out straight, which may be done with the aid of a straightedge, and also by giving it a slight draw lengthwise.

"When this is done, proceed to apply the webbing to the top and mark the places for the seams with small tacks, which are left projecting. Then take the quarters, if dry, and draw them over the bows in the usual manner, being careful to mark each seam. Then snap the chalk line between the various marks, which will afford sufficient curve. Take to the bench and cut to chalk line, allowing half inch for the seam.

"Proceed in a similar manner with the roof piece, after which the top is ready for seaming up, which is usually done on the sewing machine. The top thus prepared, proceed to stuff by applying one light layer of hair, which is sufficient for any top.

"Some trimmers do not use any hair, and make a smooth top. Cover the hair with light-weight muslin, and the top will be ready for the final drawing, which is similar to the drawing of any other top, differing only in respect to the care taken to obtain a smooth job. As a precaution, the seams should be dampened, lest there should be some fullness, as moistening leather shrinks any wrinkles that may be there. By the above explained method the wrinkles will be successfully avoided."

Dismounting the Exhaust Manifold.



Whenever it is necessary to dismount the exhaust manifold and the piping connecting it with the muffler, it is well to smear the threads of the studs and bolts with a liberal coating of graphite paste, formed of flake graphite and "hard oil," or some other grease. This will prevent rust and insure the free release of the parts when next it is desired to dismount them. Without this precaution, there is danger that the threads will rust in place, making it next to impossible to release them without stripping.

REDUCES WEAR OF STEERING GEAR

Increased Contact Surface in New Adaptation of Screw and Nut—Self-Renewing Feature of the Device.

However satisfactory the ordinary types of steering gear may have proved themselves in practice, the fact remains that they have sundry defects which might be remedied by slight modifications in design. Thus the average so-called irreversible type of gear because of the limited amount of contact surface in the worm and segment, of which it is most commonly composed, is subject to an inordinate amount of wear. Even

though provision may be made for compensating for this by adjusting the mesh of the two members, this is a disadvantage, which is further increased by the fact that a great amount of dependence must be placed on the very small amount of metal contained in the teeth which are in mesh. A possible modification which is of considerable advantage in this respect, is embodied in the screw and nut type of gear, of which several types are already in use. A recent development in this line, however, goes a step further than the ordinary device of this description by providing for a very great length of screw, and so, a great amount of contact surface.

The arrangement, which is shown by the accompanying illustration is that of the Birch steering gear, a British invention, which is characterized by a telescopic rod taking the place of the ordinary plain connecting rod, while the transmission from the steering column to the gear proper is through bevel gears. The bevel gears are connected to the telescopic portion of the gear through a universal joint, allowing for weaving in the frame, and the screw is enclosed in a dust and dirt proof casing.

By employing a divided sleeve, or nut, provision for adjustment to compensate for wear is made. The two halves of the nut may be brought together by means of suitable nuts and studs, so that the amount of grip of the nut upon the worm may be altered at will. Each of the sections is flanged, and by shifting the flanges over one another the two halves may be rotated slightly to bring about the desired effect. An option in the construction of the transmission from the column to the gear proper is the use of skew gears, as shown in detail at the side of the illustration.

A further point which is noteworthy in this connection is that instead of the usual segments, complete gears are used in the transmission. The object of this is to provide ready means of renewal for wear. The gears are mounted on squared shafts. By releasing the fastenings and shifting them about, a quarter turn at a time, new surfaces may be presented, thus prolonging the life of the gear to a considerable extent. This feature, together with the great amount of wearing surface in the worm, is held to make the gear well-nigh indestructible.

Replacing Tube in Clincher Tire.

When replacing the tube in a clincher tire care should be taken to clear the inside of the shoe of all dirt and dust, as the chafing incident to the presence of any grit which may remain is very deleterious to the inner tube. In doing this it is not sufficient merely to scoop out the dirt with the finger ends, after having tapped the cover lightly around the outside. The inside should be mopped out with a dry rag, after which any remaining particles may be gotten out by slightly moistening the rag and sopping them up. Subsequently a good dusting with powdered chalk should be given the cover.

A simple test for determining whether the muffler is clogged in such a way that the exhaust is escaping through leakage at improper points, is to place the toe of the boot over the discharge pipe, momentarily, while the engine is running slowly under throttle control. If the only exit for the waste gases is through the proper channel, the effect will be to slow the motor.

ACTUATION OF SLIDING GEARSETS

Relative Merits and Demerits of Selective and Progressive Methods—Source of Difficulty and the Remedy.

One of the great advantages of the selective method of operating sliding gearsets is that the shifting lever may be thrown clear back in either of its slots with the absolute certainty that the gears will be drawn into their proper position—providing only that the mechanism is in good order. In this respect it represents a considerable advance over the progressive method of actuation, in which a certain amount of skill is required in selecting the notches, when making a quick change of gear, unless some special automatic contrivance is provided to release the catch when passing from one gear to another. By that very token, however, the selective type of change gear is robbed of one of the advantages possessed by the other type. For the positive lock afforded the progressive type of lever is replaced in the selective type by a series of automatic fingers or latches, which are intended to retain the pull-out, or gear striking rods, in the position selected by the lever. In some types of transmission, this provision is further supplemented by the use of a special form of interlocker which secures permanently the rods which are not for the moment engaged by the lever.

A fault which exists in this type of transmission, no matter how well made, once it has been permitted to get out of order, is that the gears develop a tendency to "jump" out of mesh when the car takes an obstacle in the road. This difficulty is caused through some fault in the latches which nominally hold the gear striking rods, except when being forcibly actuated by the lever. Sometimes the springs become weakened through continual use, but more often it happens that the notches in the rods become fouled with dirt and grease, or that the cases in which the latches and springs are enclosed become fouled in the same way, so that the latches fail to engage. A rare, though possible source of this difficulty arises also through the connecting mechanism between the lever and rod becoming disarranged, so that the rod is drawn into its proper position when the lever is thrown clear back in its slot.

While the difficulty arising from the tendency of the gears to jump out of mesh in this way is not necessarily a serious one, yet there are times when it is productive of injury to the gears as well as inconvenience to the driver, so that it is important that it should be prevented. In order to do this, it is only required that the latches be kept in order—a thing which may be done readily enough, if they are subjected to sufficiently frequent inspection and cleaning, which is well bestowed, by the way, upon any part of the mechanism.

SPOKANE HOLDS FIRST CLIMBFEST

Contest Preceded by a Big and Beautiful Parade—Spirited Events on the Monroe Street Hill.

Preceded by a parade of 60 decorated cars led by a truck containing a brass band of 20 pieces, Spokane's first hill climbing contest, held in that city on Tuesday of last week, 14th inst., was a big event in the sporting history of that northwestern city. The hill climb was held on the Monroe street hill, 1,800 feet long with a rise of 166 feet.

The decorated parade which raised the curtain on the real competitive events was worth witnessing. There were more than 150 cars in line and of this number 60 were decorated. A number of non-competing cars were picked up along the route of march to the hill climb.

The Overland car, driven by Mrs. M. L. Wilson, won the first prize for decorations. The car was smothered in pink and white sweet peas and carnations, with a floral lap robe and the name of the car designed in flowers across the front. Second prize went to Mrs. A. L. Horenburg, whose Maxwell was a symphony in evergreens and scarlet crimson rambler roses. Fred Stone's Buick, which was decorated with poppies, roses and greens was adjudged fourth, and John Sengfelder got a pair of gauntlets when his Haynes car was picked fifth. Flags and bunting were its decorations.

The hill climb on Monroe street attracted a large crowd and especial interest centered in the free-for-all event, as the prize was a beautiful silver cup. Arthur Engquest, driving a Thomas-Detroit, covered the incline in 48 seconds and the nearest approach to that time was made by the Inland Motor Co.'s Stevens-Duryea, which was clocked in 58⅘. In the tryouts of the winning cars the Thomas-Detroit reduced its time to 45 seconds, with the Stevens-Duryea a few seconds slower. This latter car won in the class for cars between $2,000 and $2,500.

Dr. R. H. Hahn, driving a Ford, won the handicap event for cars selling for less than $2,000 when he climbed the hill in 1:32⅖, and he also won a victory in the class for cars under $1,000 in 1:34⅖. The class for cars between $1,001 and $1,500 went to J. T. Cronin, who drove a Maxwell. His time was 1:33⅕. M. J. Brayton, Oldsmobile, made the best time in the class for cars between $1,501 and $2,00, the watches registering 1:03⅕.

New Coast to Coast Record.

With the aid of a fellow student at Yale and a chauffeur, C. T. Crocker, a young Californian, has succeeded in establishing a new transcontinental record for a car driven by a single crew. His time from New York to San Mateo, Cal., was 20 days. Leaving New York on June 25th, he reached his destination on the 14th, inst., in 18 days running time, having lost two days at Cheyenne, owing to a broken wheel, which was rebuilt by a local wheelwright. The car used was a 1907 Fiat, in touring form except for the addition of fuel and oil tanks of large capacity, and skids in place of the usual mudguards. Practically no spare parts were carried, but plenty of mud tackle and a camping equipment were available.

The best time ever made from coast to coast by a car handled by a single crew without relay running was 33 days, until a month ago, when J. M. Murdoch, in his 30 horsepower Packard touring car, came from Los Angeles to New York in 32 days, with seven passengers, including two women and three children in the car. He laid up seven days on the road and made the trip in 25 days actual running. Crocker improves on this by 12 days gross time, and seven days running time. He comes within 5 days of the 15-day mark made by L. L. Whitman and a crew of five men, in the Franklin car, when Whitman and his men drove night and day in relays.

New York-Paris Race Near Finish.

Technically behind the American Thomas car in the New York to Paris "race," the German Protos car is, so to speak, "on its native heath," having entered the domain of its Kaiser. Before leaving Moscow on Tuesday last the car was stripped for speed, and, as its progress in Germany will probably be expedited as much as possible by the patriotism of "Vaterland," it is a safe bet that it will be the first of the contestants now on the road to reach the French capital. The Thomas car has had hard luck in Russia. It strayed to Viatka through misdirections given by Russians unable to understand signs, and on Wednesday night was 30 hours behind the Germans. While the American car has a big allowance of time because of its trip to Alaska, the handicap is unlikely to count in European summing up of the contest, and the German Protos car, should it escape accident and maintain its practical lead into the French capital, will be hailed on the other side of the big pond as the victor. Lieutenant Koeppen, its master spirit, already wears the imaginary laurel of the conqueror, in the estimation of the German people. The Zust Italian car is reported as having just reached Tomsk, in Siberia.

Proud of Its "P. S." Performances.

While "P. S." usually means the main part of a woman's letter, the Studebaker Automobile Co., of South Bend, Ind., has given it a new meaning by issuing an elaborate document with the significant abbreviation on the outside in red ink. In this connection it means "perfect score" and the printed matter on which it appears, when unfolded gives the details of fourteen notable races and road events in which Studebaker cars have won the "P. S."

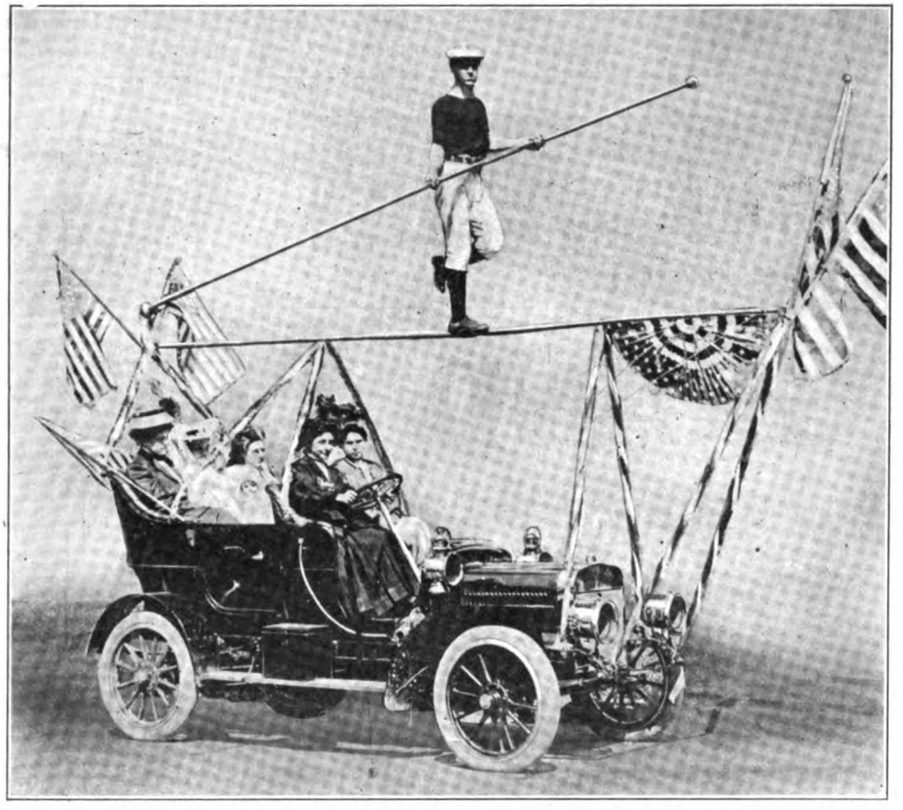
LOWELL REVIVES RACE PROJECT

City Daddies Grant Use of Streets on Labor Day—Tyngsboro Selectmen also in Favorable Mood.

The project of a big automobile race at Lowell, Mass., nipped as the bud was ready to bloom just before the Fourth of July, has been revived and Labor Day is the new date fixed for the contest. The Lowell Automobile Club has secured permission from the board of aldermen to use certain streets in Pawtucketville for a race on that date. The city clerk is authorized to grant permits to automobile owners, not exceeding 12, to exceed the speed limit on that day in Pawtucketville or on any day to which the race may be postponed. The streets upon which the race will take place will be closed to other public travel on the day of the race.

As part of the roads to be used as a course for the race lie within the town limits of Tyngsboro, it is within the power of the selectmen of that town to forward the project or to leave it up to the Lowell authorities to provide a course wholly within the city limits. The selectmen are favorable in their attitude. At a hearing which they gave the only remonstrance was based on the matters of guaranteeing the townspeople against personal or property damage and the town itself against any expense for road repairs made necessary by the race. President Heinze and Secretary McKenna, of the Lowell Automobile Club, gave assurances concerning these matters and the selectmen referred the question to the town counsel, whose opinion will determine their final action.

Demonstrating Speed for City Solons.



For the purpose of illustrating to the local legislators that the provisions of a new traffic ordinance, introduced in the board of trustees last week, will safeguard pedestrians and general traffic, members of the Sacramento (Cal.) Automobile Club put their cars at the disposal of the city's solons and demonstrated how fast they would be permitted to go if the bill was passed. The ordinance was framed by the automobile club and is a copy of the Los Angeles ordinance. It fixes the speed limit of 12 miles an hour for automobiles in the downtown congested districts, while twenty miles is the limit for the residence sections. Apparently the plan was as successful as it has been in numerous instances of a like nature. The trustees were unanimous in the opinion that the 8 miles limit is far too slow for the business section, and expressed the belief that 12 miles is none too fast. With regard to the outside streets, however, none of them was willing to subscribe fully to the 20 miles limit, as that seemed to them to "hit it up too fast."

ACROBATIC FEATS ON RUNNING CAR

Clever Agent Utilizes Circus Parade for Odd Demonstration—Declines Invitation to "Go with the Show."

While automobiles have been used for many purposes for which they never were intended, the recent "stunt" of a citizen of Saginaw, Mich., is worthy of special notice, if for no other reason than because of its originality. The "stunt" in question, which furnished a striking illustration of the smooth running qualities of the friction driven Carter car, for which he is local agent, was performed by E. D. Doan. Doan took a car from stock and rigged up a horizontal pole over it, by bracing the latter on the ends of the frame and at the rear of the tonneau reinforced by braces so attached to the sides of the tonneau as to prevent either lateral movement or vibration from side to side, as shown in the accompanying illustration.

CIRCUS STUNTS TO SHOW THE CAR'S SMOOTH RUNNING

The psychological moment for Doan to demonstrate by the use of his attachment, the smooth running qualities of his car came when Ringling Brothers' circus arrived in town. Having secured the services of the 15-year-old daughter of a townsman to drive the car, he entered the machine in the usual "parade," while he, on top of the car did "tight rope" acts on the horizontal bar, balancing himself by the aid of the usual pole. The difficulty of the feat was further increased by the fact that the slightest jerk would have thrown him down among the passengers who comprised, in addition to the "chauffeuse," four ladies and a wee baby.

The demonstration passed off without mishap, however, and was successful in attracting the desired amount of attention to the car as well as to the enterprising performer. So thoroughly pleased with the performance were the Ringling Brothers, that they made an offer to Mr. Doan and his young driver to go with them for the remainder of the season. Doan felt that he could not leave his business, but consented to the extent of following the show to Bay City, where he appeared in the parade the following day.

Dust Laying Experiment on Streets.

Mayor F. D. Stafford, of North Adams, is practically certain to adopt a new method of street sprinkling on certain streets in that city that is believed to involve a solution of the dust problem. This is a method by which it can be used in an ordinary sprinkler, the fluid to be poured on the street and then sanded. The theory is that a street makes its own dust and with the coal tar coating over a street no dust can be made. The mayor is investigating and will probably try the experiment on three miles or so of the streets of that town. It is estimated that the cost of the method is about $300 a mile. One dressing does a year.

WHEN OWNER IS NOT RESPONSIBLE

Court Says He Isn't Liable for Accident Caused by Chauffeur to Whom He Lends His Car.

The owner of an automobile cannot be held responsible for injuries inflicted upon a third person by the vehicle when the chauffeur is driving the car for his own purposes without the owner's presence. Such is the law as interpreted by the Appellate Division of the Supreme Court of the State of New York, and the decision goes so far as to absolve the owner from legal responsibility even when he has consented to such use of his car. Justices Clarke, Ingraham and Scott concurred in this decision, Justices Houghton and McLaughlin dissenting.

George Cunningham sued Burton S. Castle for damages for injuries sustained in being run down by the defendant's automobile at Eighty-first street and Central Park West on September 19, 1904. In the lower court it was shown that the automobile was being driven by Harry Boes, Mr. Castle's chauffeur, who had received the owner's consent to use the car for "an hour or two" for his personal pleasure of business. A jury awarded a verdict for the complainant. The decision on the appeal reversing that finding and ordering a new trial, read by Judge Clarke, held in part:

"It is urged that the automobile was a dangerous instrumentality, and that, having been intrusted to the chauffeur, the liability of the master still attached, because of its dangerous character. The automobile is not necessarily a dangerous device. It is an ordinary vehicle of pleasure and business. It is no more dangerous per se than a team of horses and a carriage, or a gun, or a sailing boat, or a motor launch.

"If the gamekeeper had borrowed his master's gun and had gone from the estate on a hunting expedition of his own and had negligently shot a man, would the master be responsible because he was using that instrumentality, which might be dangerous if carelessly used, the gun?"

The dissenting opinion held in part:

"While a powerful automobile may not, strictly speaking, be deemed a dangerous instrument, it may become so if recklessly driven. They are so dangerous that the Legislature has prescribed that their ownership must be registered and the driver licensed, and that speed in different localities must be regulated. The defendant recognized this when he instructed his servant to be careful on the trip which he permitted him to make. If a railroad official should loan a locomotive to one of the company's engineers for the purpose of hurriedly visiting a distant locality, it could hardly be said that the engineer alone would be liable for injuries inflicted upon third persons."

CEYLON PLANTATIONS NEED CARS

They Must be Good Hill Climbers, Says Consul Creevy—Peculiarities of the Cingalese Roads.

Although Ceylon at present boasts but one American made automobile among the 200 or more cars which are in use upon its highways, American Consul E. A. Creevey, of Colombo, sees possibilities in the market which are not to be ignored. Incidentally, he furnishes some advice which is of general value to exporters trading in other fields of commerce with foreign countries as well as to the possibilities presented by the tea and rubber producing island in the Indian Ocean.

"At present there are a few less than 200 automobiles in service in Ceylon, only one of them of American make," he remarks. "It would appear that there is need for several hundred more machines here, but whether the need would be recognized by those expected to purchase is a question. The field which, it is believed, could be developed profitably by automobile manufacturers, lies in the tea and rubber estates, of which there are about 1,200 on the island. Each estate needs an automobile, but as yet very few of the proprietors have taken steps to meet the want.

"The machine required in Ceylon should be a good hill climber, of moderate cost, and economical in operation. The vast majority of the plantations are situated in the mountains, and are reached by narrow, almost spiral roads, with heavy grades and sharp turns. It should be simple of operation and so constructed as to respond quickly to the touch of the chauffeur, as the driver of a car on a Ceylon mountain road is liable at any instant, in making a sharp turn, to find himself confronted by a heavily laden buffalo cars occpying the whole width of the road, and with a rocky wall on one side and a precipice on the other. The Colombo price of gasolene is 50 American cents per gallon, hence a successful car in Ceylon would necessarily be one using the minimum of that fluid.

"If the American automobile manufacturer entertains the idea that his machine may be sold in Ceylon by catalogue, let him dismiss that idea forthwith. Automobiles may be sold here only as the result of demonstration. The manufacturer, though he be thoroughly satisfied of the excellence of his car, cannot expect a contemplating purchaser, 10,000 miles or more removed from the sight of that car, to understand its capability as he does himself, with nothing but a printed catalogue to guide him. He should remember that in the development of his car he himself refused to accept the statement of his factory foreman as to the performance of any part of it, and was convinced of the truth only after the car had been taken out over the road and the working of the part referred to demonstrated.

"The American automobile manufacturer contemplating the capture of the Ceylon market should begin by sending out a representative and a fair sample of his machine, authorizing his representative to assure a purchaser that a supply of parts would be kept at Colombo. This last consideration is essential in the case of a machine the various parts of which are not standardized, as it is not to be assumed that a resident of Ceylon would knowingly place himself at the disadvantage of having to wait for a substitute part of his machine, in case of damage by accident, to be shipped from the United States."

Safeguard Against Leaky Pipe Joints.

To ensure permanence and positive avoidance of leakage, it is recommended by a foreign expert that pipe joints which are to be closed with asbestos-lined copper gaskets, be made up with a paste of graphite or black lead, and boiled oil. In this connection care should be taken not to daub the mixture on any threaded portions of the joint or its connections, as the paste becomes very hard after it has been permitted to set.

VILLAGE COP SHOOTS UP A CAR

One of His Bullets Hits a Female Passenger—War Between Chicago Club and the Town Officials.

There is a duel on—if not "to the death," it threatens the penitentiary—between the Chicago Automobile Club and the village authorities of Glencoe. Of course, neither of these two bodies would be consigned to the gloom and hardships of prison life should the battle be to the possible finish; but they would be represented in the one case by T. P. Henderson, a member of the club, and in the other by Frank Moore, a special policeman, employed, with several others, by the village to enforce the automobile speed regulations on Saturdays and Sundays.

Henderson was passing through Glencoe in his motor car on Sunday, 12th inst., with several friends as passengers, his route leading him into a "trap" whereat Moore was the presiding genius. He failed to bring his car to a stop when commanded so to do and the cop proceeded to unlimber his shooting iron and make a target of the vehicle. One result of his little "schuetzenfest" was that one of the bullets, undoubtedly intended for the tank, struck Miss Buena Stribling, who was among Henderson's guests in the car, and she escaped injury only through the remarkable good fortune of wearing a pearl button on the spot where Moore's leaden messenger landed and glanced off.

As a sequel to this near tragedy the village authorities of Glencoe have threatened to put Henderson into the penitentiary for an "assault with intent to murder," while the Chicago Automobile Club has determined to prosecute Special Policeman Moore and qualify him for wearing a prison suit because of the shooting of Miss Stribling. Both sides will make a vigorous defense of the respective defendants in the proceedings, and it is evident that there is an abundance of acrimony to give to the trials a gingery tone. The village will base its serious charge against Henderson on the statement of Special Policeman Moore, who declared that when he stepped out into the middle of the road, showed his star, and ordered Henderson to stop, he neither slowed up nor turned out, but headed his machine straight for the officer. The policeman says he dodged out of the way just in time to escape being run down and that he fired two shots in the air before he aimed at the gasolene tank and fired the shot which hit Miss Stribling.

"The aiming of a large automobile going at the rate of over 20 miles an hour at an officer of the law in the discharge of his duty certainly is an assault with intent to kill," said Village Attorney Morton T. Culver, of Glencoe. "It is especially reprehensible when it is considered that it was done by a man charged with crime and a man several times convicted of crime. We are going to swear out a warrant for his arrest charging him with a felony, and we are going to try to send him to the penitentiary as a warning to reckless motorists."

On the other hand, Henderson declares that Moore's act was a "clear case of a policeman's officiousness," and he adds: "It was a regular hold-up. We were not violating the speed ordinance, so there was no reason why we should have stopped to satisfy the whim of the policeman. The speed limit in Glencoe is, I believe, 15 miles an hour. We were running at less than a 12-mile rate, and I knew it positively, so I paid no attention to the wave of the officer's hand."

In support of Henderson's declaration a number of other automobilists have declared that the village of Glencoe is practically "frying fat" out of the motorists, President Ira M. Cobe, of the Chicago Automobile Club, going so far as to openly invite prosecution for slander involved in his unqualified assertion that the whole thing is a matter of graft between the special policemen and Justice of the Peace M. T. Lane. In fact, some of the automobilists who hope to send Moore to the penitentiary hope to involve Lane also in the disaster, and to deprive him of his commission even if they fail to send him to prison.

It is asserted that the village of Glencoe makes a very good thing out of its war against motorists. Since January 1st there have been 76 automobile arrests, in which total fines of $1,230.50 have been imposed. During the six months between January 1 and July 1, the regular salary paid to the village attorney—a retainer of $20 a month—and $55 a month to Policeman Dennis—the one regular officer—amounted to $450. In addition approximately $200 was paid out during May, June and July to Frank Moore, J. R. Culver, Roland Herfurrd, James Brandl, L. C. Conrad and Harry Ford, who acted as special policemen on Saturdays and Sundays in the campaign against the motorists. The special men were paid at the rate of $10 a day, while they served, so it is evident they are expected to pay for their "salt."

Palestine to Have Automobiles.

As a result of the first practical example afforded Palestine of the success of the modern motor car, a great deal of local interest has been aroused, and several people are planning to purchase cars, it is reported by the American Consul at Jerusalem. The "demonstration," which was wholly incidental to the pleasure tour taken by a party of American travelers, passed off successfully, even roads that had been pronounced impassable to the car being traversed without difficulty. In order to enter the sacred precincts of the Holy Land, it was necessary to obtain permission from the Turkish Imperial Government.

NEWARK CLUB AVOWS LOYALTY

Rumors of Probable Secession from State Federation Set at Rest—Fight Against Frelinghuysen Law Approved.

Rumors current to the effect that the New Jersey Automobile and Motor Club of Newark contemplated withdrawal from the Associated Automobile Club of New Jersey were finally set at naught by action taken by the board of trustees on Thursday evening, 16the inst. The meeting was an extended one, and all the matters included in the rumors, including one to the effect that the members of the club disapproved of the movement to test the Frelinghuysen law, finally were disposed of by the adoption of the preamble and resolutions which follow:

Whereas, Statements have recently appeared in the press representing that the New Jersey Automobile and Motor Club was about to sever its relations with the Associated Automobile Clubs of New Jersey and also its relations with the American Automobile Association, and

Whereas, Statements have also appeared that this club was not in accord with the policy of the Associated Automobile Clubs of New Jersey in testing the constitutionality of the law; therefore be it

Resolved, First, That this club is and always has been loyal to the Associated Automobile Clubs of New Jersey and expects to remain so, believing that the fundamental principle of organization is absolutely necessary for the success of all undertakings.

Second, That this club is in hearty accord with the management of the American Automobile Association and has no intention whatever of severing its relations with the association, but desires to co-operate with it in its efforts to better automobilists and automobile interests.

Third, That this board is in hearty accord with the proposed suit to test the constitutionality of the law, and to subscribe its necessary pro rata share of the expense of same in compliance with the wishes of the members of the club as expressed by a resolution unanimously passed at the annual meeting of the club on May 4, 1908.

Fourth, That copies of these resolutions be sent to the secretaries of the American Automobile Association and Associated Automobile Clubs of New Jersey, and to the press.

Rockefeller to Become a Real Tourist.

The opportunity of selling him his own gasolene at outrageous rates may be presented to those garage men who are fortunate enough to be called upon to replenish John D. Rockefeller's touring car, which it is thought he is going to use for a more or less extensive trip this summer. Heretofore the oil king has confined himself chiefly to runabouts and limousines, but the recent purchase of a White steamer, of the strictly touring car pattern, coupled with a request to the White touring bureau for maps, road data, and license information, has given rise to the belief that he is going to become a real automobile tourist.

The Week's Patents.

886,701. Change Speed Gear. Peter Hesselius, Chicago, Ill. Filed March 5, 1907. Serial No. 360,651.

1. In a variable speed power transmitting device, the combination with a driving shaft, and a driven shaft, of means for imparting rotation from said driving shaft to said driven shaft, said means comprising a plurality of gear wheels mounted for separate rotation on one of said shafts and means for non-rotatively securing said gear wheels to their shaft, said latter means comprising a radial notch in the bore of each gear wheel, radially movable keys mounted in the shaft, and a longitudinally movable bar mounted in the shaft and provided with a slot adapted to receive said keys.

886,738. Transmission Gear Casing. Angelo Tedeschi, Milan, Italy. Filed July 10, 1907. Serial No. 383,085.

1. In a gear casing for draft gears, a continuous frame adapted to encircle the gears, and a light sheet metal cover inclosed and supported by the frame.

886,760. Carburetting Mechanism for Internal Combustion Engines. Alanson P. Brush, Detroit, Mich. Filed Feb. 3, 1906. Serial No. 299,281.

1. In a fuel feeding device for internal combustion engines provided with a mixing chamber or air passage, a fuel reservoir discharging into the mixing chamber, a valve for controlling the discharge of the fuel into the mixing chamber, a balanced air valve for controlling the admission of air into the mixing chamber for atomizing the fuel, and means to adjust said air valve to vary the quality of the mixture at low speeds without materially varying the quality of the mixture at high speeds.

886,835. Means for Attaching Pneumatic Tires. Amos C. Miller, Chicago, Ill. Filed Aug. 23, 1905. Serial No. 275,423.

1. The herein described means for securing a pneumatic tire to a vehicle wheel, comprising a metallic wheel rim having a circumferentially depressed tire seat centrally located, a marginal inclined or beveled seats in combination with a pneumatic tire having a base portion adapted to said central seat and lateral flanges adapted to said inclined seats, and contractible retaining bands seated upon said flanges and adapted to clamp the base and flanges to their respective seats, substantially as described.

886,911. Variable Speed Gear. William Wolter, Burress, Neb. Filed Oct. 4, 1907. Serial No. 395,901.

1. In a friction transmission gear, a driven shaft, and plurality of driving shafts arranged around the same, a cone upon the driven shaft, oppositely disposed cones upon the driving shafts, interposed discs between said cones, and means for shifting said discs longitudinally of the cones, substantially as described.

886,990. Motor Driven and Steered Fore Carriage for Automobiles. Louis Krieger, Paris, France. Filed Jan. 10, 1906. Serial No. 295,502.

1. In a vehicle, the combination, with an axle, and an axle sleeve pivoted to the axle and provided with hub-bearings at each side of the pivotal point, of a wheel having a hub journaled upon the said hub-bearings, a motor carried by the axle sleeve, and gearing intermediate the wheel and motor whereby the wheel is driven.

887,001. Transmission Mechanism. Louis E. Mahout, Paris, France. Filed Jan. 22, 1906. Serial No. 297,193.

1. An apparatus for the transmission of motion applicable to automobiles, characterized by the combination of two cones, arranged in front of one another, a shaft upon which the driven cone is slidably mounted, a belt connecting the two cones, two pinions of different diameters movable along the shaft of the driven cone, a driven shaft, and two toothed wheels carried by the driven shaft and with which the two pinions can be thrown into mesh, substantially as described.

887,002. Cushion Attachment for Automobiles. James E. Marriner, Newton, Mass. Filed Jan. 7, 1907. Serial No. 351,130.

1. The combination with a longitudinal supporting bar of a vehicle body, the axle, and a spring secured at its center to the upper face of the axle and having its ends secured to said bar, of a socket block secured upon the upper face of the spring directly above the axle by the means securing the spring to said axle and having a hollow piston projecting upward therefrom, a second socket block secured to the lower face of the supporting bar and having a cylinder projecting downwardly therefrom freely receiving the piston, a cushion ring between the socket blocks and surrounding the piston and cylinder of the socket blocks, and toggles connecting the socket blocks at diametrically opposite sides, between the supporting bar and spring.

887,013. Hydrocarbon Engine. James W. Packard and William A. Hatcher, Warren, Ohio, assignors, by mesne assignments, to Packard Motor Car Company. Filed Feb. 12, 1902. Serial No. 93,755.

The Dependable Quality of the

1. In an explosive engine, the combination with the cylinder of a water jacket surrounding the cylinder and securely connected at its ends to the ends of the cylinder, said water jacket having a series of transverse or annular corrugations, whereby opening of the joints between the jacket and the cylinder due to relative expansion and contraction is prevented.

887,117. Shock Absorber. William Parfrey, New York, N. Y. Filed Dec. 28, 1906. Serial No. 349,781.

1. A shock absorber comprising a shaft, a toggle joint connected therewith, and springs on said shaft adapted to limit the movement of said joint in either direction vertically.

Studebaker

RECORD FOR JUNE

Perfect Score In the 24 hour endurance contest at San Leandro, Cal., under the auspices of the Frisco Automobile Club, a Studebaker "30" Model H stock car finished with a perfect score, **and was the only contestant to run the entire 24 hours without stopping its motor.**

Perfect Score In the Wilmington, Delaware, Sealed Bonnet Contest, held June 27th, a Studebaker "30" entered, finished with a perfect score.

Perfect Score In the Stroudsburg, Pennsylvania, Endurance Run, June 27th, the Studebaker "30" finished with a perfect score.

Studebaker Wins In the Hundred Mile Road Race at Portland, Oregon, June 4th, over a 14.5 mile course, the two Studebaker cars entered won first and second place in competition with ten other cars. The winning Studebaker covered the 100 miles in 2 hrs. 4 min. 8 sec.

Studebaker Wins June 27th, in the Hill Climb at Delaware Water Gap, Pennsylvania, the Studebaker made the mile climb in 2 min. and 2 sec., winning the event.

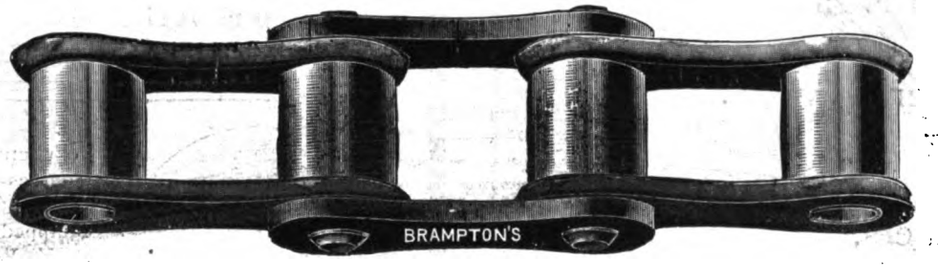
¶ Schrader Motor Tire Valves, as shown in cut, are the regular equipment for G & J Motor Tires, Hartford Dunlop Detachable Tires, Fisk Detachable Motor Tires, and New Goodyear Detachable Motor Tires.

¶ Our No. 777 Motor Tire Valve is the standard for 2½ inch and 3 inch Tires and our No. 725 Motor Tire Valve is the standard for tires larger than 3 inches.

Supplied to the Trade by All Tire Manufacturers



Manufactured by **A. SCHRADER'S SON., Inc., 28-30-32 Rose St., New York**

Digitized by Google

Large Sales

make it possible for us to import **THE CELEBRATED BRAMPTON CHAINS** from **ENGLAND** (paying freight and duty), and sell them at the same price at which the several other automobile chains are sold to manufacturers, jobbers, dealers and users.

THE BRAMPTON MOTOR CHAIN

All side plates on both sides on the Brampton Chain are stamped **"BRAMPTON."**

LARGE SALES and SMALL PROFIT with thousands of satisfied customers is our best advertisement.

THE BRAMPTON CHAIN is made of helf-hardening Steel; the strongest Chain in the World. All parts polished; fits sprockets (that are properly cut) without friction.

Some of the other chains may look like **THE CELEBRATED BRAMPTON CHAIN** because some of the other chain makers began to copy the design and shape of the **BRAMPTON CHAIN** links in 1904. They have improved somewhat on their copied design from time to time until these chains now look more like the **BRAMPTON CHAIN** than ever before. These chains somewhat resemble the **BRAMPTON** in appearance, but the manufacturers of such chains have been unable to copy the material—self-hardening steel.

NO CHANGE IN THE BRAMPTON

There has been no change in the design, construction, material or finish of the **BRAMPTON MOTOR CHAIN** in the past ten years.—**"ENUF SED."**

PRICE

The price being equal, it's presumable you want the best, and full value for your money. In such cases, the **BRAMPTON FILLS THE BILL**, and the prices are the same to manufacturers, jobbers, dealers and consumers as any other chain of equal size—as follows:

CHAINS TO FIT AMERICAN CARS

1 x ⅜ x 9-16—1 x ½ x ⅝—1 x ½ x 9-16 roller	$1.00 per foot.
1 x ⅝ x ⅝ roller	1.17 "
1¼ x ½ x ⅝—1¼ x ⅝ x ⅝—1¼ x ⅝ x ¾ roller	1.25 "

We also carry in stock the **BRAMPTON CHAINS** to fit Foreign Cars—Mercedes, Panhard, Martini, Fiat, etc.

Your 1908 Car

You can have the new car that you order fitted with the **CELEBRATED BRAMPTON CHAIN** if you order it that way. No extra cost to either you or the manufacturer. All standard sizes in stock to fit American and Foreign Cars at the same price as the other chains.

SPECIAL CHAINS TO FIT THE INDIAN MOTORCYCLE.

Agents wanted in unoccupied territory. Catalog on request.

We are Sole American Agents for **BRAMPTON CHAINS**, and they cannot be bought from anyone else except through our Agents.

Pan-American Automobile Body Polish

Pan-American Polish was awarded the Bronze Medal at the Louisiana Purchase Exposition at St. Louis, 1904. This polish has been carefully prepared for the Automobile trade. It is also applicable to the carriage trade, or can be used on any varnished furniture or woodwork of any kind. It will remove stains, cover scratches; leaves the automobile with its original new lustre, without being sticky or greasy. Furnished in eight-ounce bottles. Guaranteed not to harm the finest varnish. For sale by all Automobile Dealers. Price 60 cents per bottle.

The Miller Automobile Jack

The Miller Automobile Jack is a quick acting, automatic lowering jack, designed especially for automobile use, and is adapted to the factory or garage as well as to be carried as a part of the equipment on motor cars. It is high-grade and one of the finest finished jacks on the market. We guarantee this jack for twelve months. The list price of the Miller Jack, $3.50 each.

Agents in all large cities.

THE STEPNEY Spare Motor Wheel

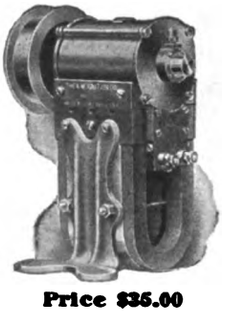
ON AND GONE IN LESS THAN A MINUTE

Punctures and other tire troubles have no terrors for the motorist whose car is equipped with the **STEPNEY WHEEL.** If a tire goes wrong it is only the work of a moment to attach the **STEPNEY WHEEL** and be off again with no further delay.

Isn't it worth having, for the peace of mind alone that it brings?

Write for Catalogue D.

Spare Motor Wheel of America, Ltd.
236 Michigan Avenue, CHICAGO, ILL.



THE K-W MAGNETO

Model F

Has bracket as shown for attaching to frame of car. Made especially

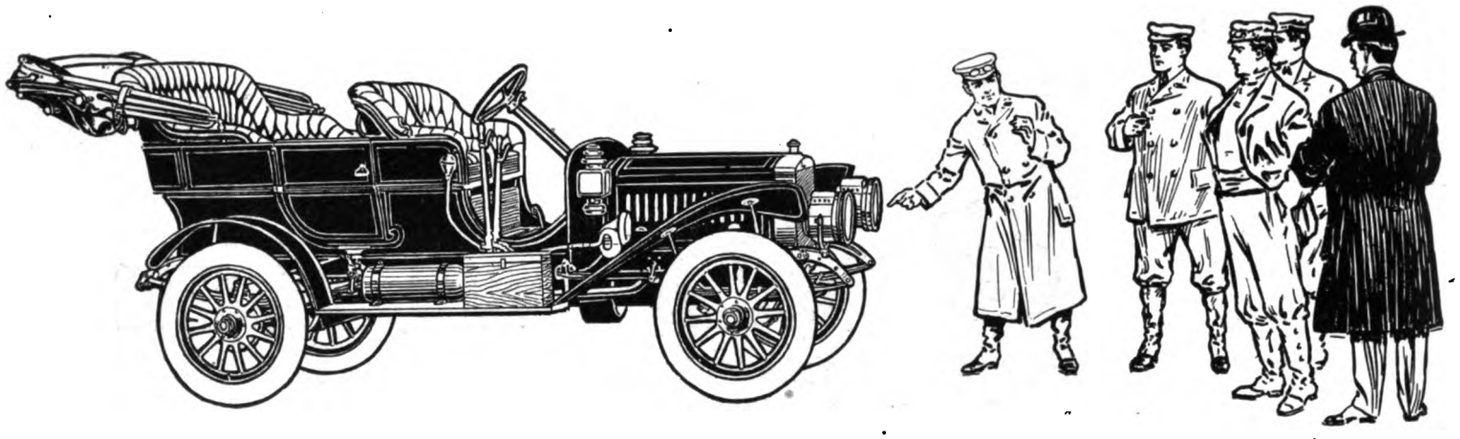
For Ford Runabouts

Good on any car.

High in Quality—Low in Cost
Perfectly Reliable—Easy to Apply
More Power—Less Fuel

Price $35.00

It starts the engine easily without batteries and runs it faster and better than any battery because it gives a hotter spark. They run in ball bearings and have no moving wires or brushes to give trouble and wear out. They are made to last and they do last. They are the cheapest that is good and there is nothing better at any price.



We also make high grade Coils and Plugs and the K-W Master Vibrator. Get our catalogue.

What a Chauffeur Knows About Automobile Prices

THERE'S going to be a grand wakin' up some day soon on automobile prices. I'm next to the game and I *know*," said a chauffeur.

He was proudly extolling the virtues of his car to his professional brothers.

"What's the use of paying from $3000 to $5000 for a motor car?—that's what I'd like to know.

"You've got to show *me* where you fellows' cars puts it over the Mitchell.

"*I've* driven your foreign cars that cost their owners $3000 duty *alone*, and I've driven *American* cars like *Johnson's* there and *Dorsen's* that set their bosses back $3000 and $5000.

"I've *lived* in cars like *them*—*slept* in 'em—driven 'em all day long—through rain storms and over roads that were *fierce*.

"I've babied 'em up hills that they absolutely refused to take on the high.

"I've taken 'em down and put 'em together in the garage.

"I *know* 'em—know 'em *all* from radiator to tail-light and if you fellows think you can *'show me'* just where your cars have got *The Mitchell* skinned, come out on the road with me and let's *see* if you can,

"The boss paid $2000 for *this* car. She's got four of the smoothest cylinders *you* ever saw and she's got *horse-power*—35—and she's done better on hills and under all road conditions than any 50 h. p. $5000 cars *I* ever saw, and I've driven 'em all and run up against *every test you can name*.

"*Your* bosses may like to pay $5000 for a car but *mine* was *wise*.

"You know there's a good *many* men in this country that shut their eyes tight on $2000 cars merely because they take it for granted that a $5000 car ought to be $3000 *better*. It *ought* to be all right—but *is* it?

"I want the chauffeur that *thinks* his car is $3000 better than the Mitchell to *prove up* with me—in *speed* or *power* or *hill climbing* or *any* old thing he thinks he's *better* at—*that's* all.

"*Yes* sir, if a man's in doubt about the *car* he wants, let him do what my *boss* did—make a 50 or a 500-mile *test* in a *Mitchell*.

"Any agent will take him out if he's interested in gettin' a car.

"That'll 'show him' what it showed my boss—and save him about $3000.

"Beg pardon, sir? Why, yes sir—write to the Mitchell Motor Car Company, 284 Mitchell St., Racine, Wis., and send 10c. for Art Catalog.

"Well, any of you fellows comin' out? I've got ten dollars in my pocket that says The Mitchell ain't $3000 behind *anybody's* car."

Mongrel or Thoroughbred?

NOW IS THE TIME for you, Mr. Thoughtful Dealer, to decide what you will sell in 1909.

WILL IT BE A MONGREL? a car assembled from parts carried together from all over the country and hammered into shape as well as may be?

OR WILL YOU SELL THE THOROUGHBRED—a homogeneous mechanical masterpiece, every single part of which is the result of the same genius that devised the whole?

"ASTOUNDING," "MARVELOUS," "WONDERFUL," are the terms with which some assembled cars are now tagged, though they are astounding, marvelous and wonderful only to the assemblers, who like Rip Van Winkle, have been dozing in the growing woods of automobiledom and who now, bewildered by the progress that has been going on, seize upon time-tried and long-established practices and herald their adoption by the assemblers as brand-new discoveries.

LET'S REASON IT OUT: On the one hand you have the assembled car, with an engine bought from one manufacturer, a frame from another, and a transmission from a third, and so on down to the last rivet. The maker of the engine, the mill in which the frames are pressed, the transmission man, all derive their separate profits, leaving no other way to the assemblers to obtain their rewards than by skimping the quality of their "product."

AND THEY DO IT—THEY MUST! When you examine some of these astounding cars you will be truly astounded on finding that the four-cylinder engine is cast in one piece and has only two main bearings, whereas the Maxwell has four cylinders and five main bearings. You know well enough that making a motor with only two bearings is equal to leaving the engine to its own devices as far as alignment is concerned.

IT WILL BE A TOUGH JOB FOR THE DEALER to convince the purchaser who is wise that some four-cylinder engines of small dimensions will develop as high as 30 horsepower—because they can't.

MAXWELLS ARE A HOME-GROWN AMERICAN PRODUCT. The use of Maxwell features in Maxwell cars was neither a heaven-given inspiration nor the aping of foreign design, but the outcome of sound engineering sense.

WHEN 10,116 MAXWELL OWNERS testify to the excellence of their cars, all of which have been sold by Maxwell dealers, then the Maxwell proposition is one that you can't afford to pass by.

BEFORE HITCHING YOUR WAGON TO A STAR it will be wise for you to find out all about a dealership for Maxwells, the success of which is past and present, instead of lying in the dark and distant future that has swallowed so many wonderful cars that have been marvelous chiefly in their complete and rapid disappearance from the field of legitimate competition.

Benj. Briscoe
President.

The above is from a photograph of the Franklin Model "D" Runabout, which lowered the Chicago-New York Record to 39 hours, 53 minutes, with an average speed of 20 miles an hour over 1,060 miles, including stops for supplies. From Cleveland to Buffalo, a distance of 214 miles, this car beat by one hour the Chicago-Boston-New York Express, which carried the relief relay of drivers.

Just how much the

TIMKEN ROLLER BEARINGS AND STEERING KNUCKLES

with which this car is equipped, had to do with making this record can be reckoned by adding up: The elimination of all friction—Saving in wear and tear on the engine, and the faith of the drivers that **TIMKEN PRINCIPLE AND TIMKEN QUALITY** insured them against break-downs and accidents. More than 60% of all the manufacturers of High Grade Automobiles equip their best cars with TIMKEN PRODUCT—There must be a reason. If you would like to know WHY, write us.

DOW TUBES

(The Best Tubes Ever Manufactured)

make a

PERFECT SCORE

in the

GLIDDEN TOUR

Dow Tire Company, Saratoga, July 23, 1908.
2000 Broadway,
New York.

I have run through the entire Glidden Tour with my Stoddard-Dayton Car, No. 107, with practically no tire trouble, using Goodrich casings and Dow Non-Deflation Tubes.

The front wheels have the same casings and Tubes with which I started, and I have not even had a pump to them since they were first inflated.

The right rear wheel has had two shoes, one having been worn to the fabric by sliding the wheels through braking on water breakers, and the same Dow Tube is in the second shoe.

The left rear wheel had the casing terribly cut by a bottle and blew out. A new casing with Dow Tube was put in and is still running perfectly.

(Signed) G. P. MOORE.

THE INCOMPARABLE WHITE

THE CAR FOR SERVICE

Write for White Bulletin No. 15

The above illustration is reproduced from the new White Bulletin No. 15, an attractive little booklet devoted to some of the more important automobile events of the last few months. The leading articles are "The New Road Record Between San Francisco and Los Angeles," "The Fort George Hill Climb," "The Quaker City Reliability Contest" and "The Harrisburg Reliability Contest." In addition to these four detailed accounts of White victories, brief space is given to the numerous minor contests in which the White has carried off first honors; also, the activities of private owners of White cars and the doings of "Government White Steamers" in this and other countries receive attention. We believe that you will find this booklet of interest.

Rambler

Model 31, Price $1,400

Other Models, $1,000 to $2,500

YOU can do all kinds of work with this car as a handy Runabout without the tonneau; then put the tonneau on and take your family or friends for a ride in a roomy Five-Passenger Touring Car.

Many exclusive features make it the most remarkable two-cylinder car in this country selling at $1,400.

The powerful engine makes it a hill climber; the long wheel and full elliptic springs provide great comfort; you glide over rough roads without a jar.

It is easy to care for and always clean because of the few moving parts and the enclosed power plant, impervious to dirt, mud and water, and oil tight with proper lubrication.

Immediate access to every working part is provided. The low cost of maintenance is due to simple construction, small fuel and oil consumption and protection of parts against injurious road material.

THE CAR OF STEADY SERVICE

A Postal will bring you the facts.

Please write your name and address and "Model 31" on a postal and mail to us today. You will not obligate yourself in the least

THE MOTOR WORLD

Volume XVIII. New York, U. S. A., Thursday, July 30, 1908. No. 18

MAMMOTH MERGER IN PROSPECT

Buick and Maxwell-Briscoe Companies Reported to be Arranging a Ten Million Dollar Combine.

A merger of the Buick Motor Car Co., of Flint, Mich., and the Maxwell Briscoe Motor Car Co., of Tarrytown, N. Y., and Newcastle, Ind., is at present in process of formation, according to reports from Detroit. No announcement of the merger has as yet been given officially, but the plans that have so far leaked out provide for a capitalization of $10,000,000 for the combined companies, an increase of $6,000,000 over the total capitalization of the companies separately.

The Buick company is capitalized at $2,000,000 common and $500,000 preferred, and the Maxwell-Briscoe company at $750,000 common and $750,000 preferred. For the past three months there has been considerable activity in the stock of both concerns, the Buick common advancing from 90 to 125, and the Maxwell-Briscoe combined from 145 to 165. There has not been much trading in the Maxwell-Briscoe stock, however, because of the fact that it is so closely held. It is thought that the old stock will participate in the division of the increase.

A report that the underwriting of the combine would be in the hands of J. P. Morgan & Co., has been officially denied by that concern. President Durant, of the Buick company and Richard Irvin, treasurer of the Maxwell-Briscoe company, have been in frequent conference this week, it is said, arranging the details of the transaction.

"Blue Cabs" to be Made at Bristol.

In order to make taxicabs and parts for the new American Taxameter Cab Co., the $1,500,000 concern whose stock flotation was announced in last week's Motor World, several of the men interested in the company have started an enterprise in Bristol, Conn., which is to be known as the Bristol Engineering Co. The organizers are Albert F. Rockwell, president of the New Departure Mfg. Co.; De Witt Page, secretary of the New Departure Mfg. Co., and F. E. Moskovics. Both Rockwell and Moskovics are directors in the cab company, of which Moskovics is also the engineer. While final organization papers have not as yet been filed, Rockwell has been chosen president; Page, vice-president, and Moskovics secretary-treasurer.

Would Put Aurora in Bankruptcy.

Bankruptcy proceedings against the Aurora Motor Works, of Aurora, Ill., have been commenced. Efforts are being made by some of the creditors to have a trustee appointed to carry the business forward, to sell the unfinished goods and to fulfill existing contracts. It is also thought possible that certain original stockholders can be persuaded to place a large amount of money in the treasury as the balance due upon the stock not paid in full. If this is done and manufacturing and selling continued for a reasonable time, the creditors will lose nothing.

Berkshire Receivership Holds.

The motion to have the receivership of the Berkshire Motor Car Co., of Pittsfield, Mass., dissolved has been overruled by Judge Bishop at Pittsfield. Attorney George A. Prediger urged the motion on behalf of the company, but opposition was presented by Attorney Joseph W. Lewis on the ground that the petitioners for the receivers should be given proper consideration.

Muncie Parts Sues Bartholomew.

The Muncie Auto Parts Co., of Muncie, Ind., has filed a praecipe in the United States court at Peoria, Ill., in a suit for $15,000 against the Bartholomew Co., automobile manufacturers in Peoria. The suit is brought by the receiver of the Muncie company, and is the result of a dispute three or four years old. Each side claims that the other owes it money.

POPE REORGANIZATION PLANS

Creditors to be Paid in Full and a New Company Created—Reduced Capitalization.

A complete reorganization of the Pope Mfg. Co., by which the creditors will get 100 cents on the dollar for their claims, together with 6 per cent. interest, is under way and will probably be completely effected before November. Since the Pope company went into the hands of the receivers one year ago, it has by their excellent management been brought to a point where its affairs will permit of all the creditors being paid in full; and the subsequent reorganization, underwritten by New York and Hartford bankers, with the co-operation of the principal stockholders, will once more place the concern to the forefront in the trade, capitalized on a reasonable basis and with its production concentrated at its Hartford and Westfield plants.

The terms of the reorganization provide for a reduction of the capitalization from $22,500,000 to $6,500,000, and the issuing of $800,000 worth of 6 per cent, mortgage notes, payable in three lots in one, two and three years, respectively, together with the creation of an entirely new company, to take over the properties and assets of the old company. The new company is to have $4,000,000 in common stock and $2,500,000 in preferred stock, and it is estimated that by operating only the Hartford and Westfield plants the earnings should be not less than $400,000 per annum. Holders of the outstanding preferred stock in the old company, amounting to $2,391,000, are to receive 75 per cent. of the par value of the old stock in new preferred stock and 83 per cent of the par value of the old stock in new common stock. To effect this will require the exchange of $1,793,250 of the new preferred stock and $1,984,530 of the new common stock. Holders of the second preferred stock in the old company get 20 per-

Digitized by Google

cent. of the value of the old second preferred stock in new common stock. To redeem the $8,625,100 worth of this old second preferred that is outstanding, will require $1,725,020 of the new common stock. The common stock in the old company will have no participating value in the new.

The owners of first and second preferred stock in the old company are to deposit their stock with the reorganization committee, which will buy in the old company's assets and properties after the receivers have paid off all the outstanding indebtedness, when the new company will be formed and the new stock issued. For its services in financing the transaction and in agreeing to buy up the $800,000 worth of 6 per cent. mortgage notes which the new company is to issue, the underwriters are to take $500,000 worth of the preferred stock in the new company, and $90,450 in new common stock.

The distribution of the securities of the new company upon its starting business would therefore be as follows:

	Preferred Stock.	Common Stock.
Syndicate for $800,000 cash	$500,000	$90,450
First preferred stock	1,793,250	1,984,530
Second preferred stock	.....	1,725,020
Balance in treasury	206,750	200,000
Total	$2,500,000	$4,000,000

For the $800,000 in cash supplied by the syndicate there is the corresponding issue of $800,000 in notes, which must be added to the preferred and common stock to obtain the total of security liabilities.

The preferred stock will be entitled to cumulative dividends at 6 per cent. from August 1, 1908, and no dividends on the common stock will be made until all back dividends on the preferred are paid up. Similarly no dividends on any of the stock will be paid until all the notes taken by the underwriters are paid.

Atlas Adding New Buildings.

The Atlas Motor Car Co., of Springfield, Mass., has just given out the contract for the building of a three-story addition to its plant on Birnie avenue. The structure, which will be a combination of wood and brick, will be ready by the first of October, and is expected to make possible a production of 600 cars a year, including taxicabs which the company is now building in addition to commercial trucks.

Stevens a Manager for Midland.

Charles L. Stevens, formerly with the Hartford Suspension Co., and latterly located in Denver, returns to New York after two years, as the Eastern sales manager of the Midland Motor Car Co., of Moline, Ill. His headquarters are at the Allenhurst Garage, the New York home of the Midland.

Gibb's Tire Gets Paternal Backing.

Another new tire, having a combination of rubber and springs, is to be manufactured in Little Rock, Ark. The inventor is Fred Newton Gibb, whose father, Frank W. Gibb, an architect, has formed a company for its manufacture after having tried a set out on his car. The sheriff, several physicians and other citizenry are interested.

Hartford to Have Outdoor Show.

A pretentious outdoor automobile show is to be held at Hartford, Conn., in connection with the Connecticut fair and grand circuit races at Charter Oak Park, September 7 to 12. It is to be known as the Connecticut State Fair Association automobile show, but will be under the management of Fred W. Dart and E. G. Biddle, of the Hartford Automobile Dealers' Association. The exhibition will be given in a huge tent, with spaces for car exhibits and accessories. Electric lights and band music will help make it interesting until 10 o'clock at night.

Bennett Broadens His Territory.

The New York branch of The White company will hereafter be known as the Eastern Branch, and George W. Bennett will take the title of Eastern sales manager. The territory to be handled by the Eastern Branch comprises New York State as far as Rochester, the eastern counties of Connecticut, part of Berkshire county, Mass.; the entire States of New Jersey and Delaware, and the eastern half of Pennsylvania. The office of The White Co. in Philadelphia becomes a sub-branch under the control of Manager Bennett.

Elgin Takes Hold of Hilger's Tire.

The Elgin Automobile and Spring Tire Co. has been formed in Elgin, Ill., to make Bernhard Hilger's spring tire for motor vehicles. Capital from Elgin and from South Bend, Ind., is interested. Hilger has turned in his stock in an old company that was organized to manufacture the tire, and has taken 51 per cent. of the stock of the new enterprise. The following officers have been chosen: C. O. Lightner, president; George R. Thompson, vice-president; J. C. Kraton, secretary; and J. D. Gaylord, treasurer.

Springfield Springs a Spring Tire.

A modest 14 per cent. is being promised investors in the preferred stock of the Flexible Tire Co., of Springfield. The $100 shares are being offered in the local papers for $50 a share, and prospective purchasers are invited to take a free ride on its spring and rubber tires to assure themselves as to the merits of the invention.

Oldham Perfects a Farm Truck.

Experience among the great wheat fields and farms of Iowa has moved W. F. Oldham, the retiring president of the Auto Thresher and Implement Co., to design a motor farm truck which in addition to being able to transport farming machinery from one point to another, is also capable of supplying power to threshers, separators, corn shellers, huskers, and the like. The power plant is a four cylinder motor. Among other special features, the truck is equipped with traction wheels for country roads and "sheath" tires—not skirts—for city pavements. A company is being formed in Sioux City, Ia., to manufacture and market the truck.

Shelby Starts a New Tube Mill.

Following the destruction of the Shelby steel tube mills at Shelby, O., some six weeks ago, the new Shelby Tube Co. has been perfected by the election of the following officers and directors: President, J. C. Fish; vice-president, C. M. Skiles; second vice-president, C. S. Hook; general manager, A. C. Morse; secretary, Howard Seltzer; treasurer, James Brubaker; directors, J. C. Fish, Charles Hook, G. M. Skiles, A. C. Morse, J. A. Seltzer, Roger Heath, Edwin Mansfield, H. W. Hilderbrandt, T. J. Green, Jonas Feigher, Y. O. Peters, Robert Greer, J. W. Williams, R. P. Bricker and C. S. Moore. The total amount of capital subscribed is $250,000. The company is incorporated for $500,000.

Flexible Wheels Their Hope.

Easthampton, Mass., is looking forward to the establishment of a great manufacturing enterprise in its borders hinging around a new flexible wheel for automobiles in which a number of Springfield men are interested. The Barnett machine shop and the old Brown wagon factory are to be used for making the new wheel, according to the plans that have been announced. The company will be formally organized in Easthampton on August 28th.

Triumph Tire to be Made in Wheeling.

With an authorized capital of $1,000,000 and a paid in capital of $200, the Triumph Automobile Tire Co. is shortly to start up in Wheeling, W. Va., at a factory which has been obtained at No. 40 Zane street. The incorporators include C. K. O'Hara, of Akron, O.; Henry E. Keyes, Charles O'Deer, W. E. Johnson, of Homestead, Pa.; and K. P. Stewart, of Wheeling.

Reliance Yields to Owosso's Offers.

The Reliance Motor Co. is packing up preparatory to its removal from Detroit to Owosso, Mich. The latter town was in competition with Adrian and Lansing, Mich., in trying to get the Reliance company, but Owosso's offers finally proved the most alluring, including as they did, the purchase of some $200,000 worth of stock.

Burdick Bringing Out a New Car.

Under the name of the Burdick Motor Car Co., a new concern has been started in Eau Claire, Wis., by Ralph M. Burdick, formerly identified with the American Motor Co. The first machine to be turned out will be a six-cylinder car of 75 horsepower, to sell at $5,000, and to carry seven passengers.

COURT HOLDS UP POPE DIVIDEND

Dispute as to Money for Unzicker Claims—Appeal of Disallowed Claims—Patent Licenses Permitted.

Vice-Chancellor Howell has reserved decision on an application by Sherrerd Depue, as counsel for the Pope Mfg. Co. receiver, to pay a second dividend of 25 per cent. to creditors whose claims have been approved. There was no opposition to the payment of a second dividend, but the proposed setting aside of an equal proportionate share to await the determination of what is known as the Unziker claim, which amounts to $262,000, was opposed by Mr. Depue, and on that account, the main question was held in abeyance. When the first 25 per cent. dividend was authorized the sum of $65,000 was ordered paid into court to be held pending a settlement of the Unziker claim, which had been disallowed, both by the New Jersey and the Connecticut receivers.

Gilbert Collins, of Jersey City, asked that this be done again, saying that funds had been transferred from the Connecticut jurisdiction to that jurisdiction expressly for that purpose.

It was disclosed that the receivers have available for the payment of a second dividend o total of $454,000, that sum being made up of a balance of $241,000, after the payment of the first dividend, $130,000 from the sale of Columbia Steel Co. stocks, and $300,000 received by transfer from the Connecticut jurisdiction. The payment of a 25 per cent. dividend will take up $380,000 while the setting aside of the same proportionate share for the Unziker claim will require $65.000 more, making a total of $445,000, thus leaving a balance of $9,000 in the hands of the receivers.

Mr. Depue argued that there was no necessity of tying up a further sum of $65,000, inasmuch as there was no question but that there would be sufficient assets available for the payment of the Unziker claim in the event of its being allowed. The Hartford plant, Mr. Depue said, was alone worth $..-500,000, to say nothing of the Hagerstown (Md.) and Westfield (Mass.) plants, while the remaining claims, after the payment of the proposed dividend, would aggregate only about $800,000.

Vice-Chancellor Howell signed an order limiting to 30 days the time in which claimants, whose claims have been disallowed by the receivers, may appeal. The claimants named in the order are: Beech & Sweet, Curtin Williams Auto Co., C. H. Childs & Co., Dodge Motor Vehicle Co., Fickling & Co., Quaker City Auto Co., Louisa A. Unziker and others, and B. F. Goodrich Co.

Another order, signed by the vice-chancellor, authorizes the receivers to execute a license agreement with the Associated Patents Co. relative to royalties for the use of clutches and brakes controlled by the National Brake and Clutch Co.

Apperson Prices are Changed.

Price changes are announced in the Apperson line of six models for the coming season. Sales Manager George H. Strout, of the Apperson Bros. Automobile Co., Kokomo, Ind., is at present on a business trip, and has already closed with old agents in three cities, including New York and Philadelphia, for greater quantities than ever before. After visiting Boston, Albany, Cleveland and other points, he will go to Colorado, "for a two-weeks loaf," and about the first of September wil start for a four weeks' trip on the Pacific coast.

The prices that he is announcing for the 1909 cars are as follows: Model O, a new car, 30 horsepower, equipped with double ignition, magneto and storage battery, and with a 3, 4 or 5-passenger body, optional, $2,450; model M, 35-40 horsepower, with 3 or 4-passenger body, optional, $3,000, and with a 5-passenger touring car body $3.350; Model I, 40-45 horsepower, 7-passenger body, $4,200; model K, 50-55 horsepower, 7-passenger body, $4,700; Jack Rabbit model, 2-passenger speed car, $5.000; and model S, 50-55 horsepower, 6-cylinder, 7 passengers, $5,500.

The model M, a recently developed shaft drive car, has proved to be quite the success that was expected, and this model, together with all the others except model O, is ready for immediate delivery. The model O will be ready about the middle of August. The new catalogue of the cars, showing all the models, will be issued early in September.

Franklin Tells Salesmen Its Plans.

Announcement that the H. H. Franklin Mfg. Co. intends making a special feature of taxicabs and commercial vehicles for the coming season was made at the third annual gathering of Franklin salesmen at the factory in Syracuse, which came to a close this week. The 1908 models were shown, and their good points explained by Designer John Wilkinson and Superintendent F. J. Haynes. A run to Glen Haven in the Franklin cars that competed in the Glidden tour was part of the social program, and the proceedings were presided over by President H. H. Franklin, G. H. Stilwell, and Designer Wilkinson.

To Choose Standard Quick Acting Rim.

Significant as the first official getting together of the Association of Licensed Automobile Manufacturers and the American Motor Car Manufacturers Association, a conference between representatives of both associations was held at No. 7 East Forty-second street, New York, on Monday of this week, looking to the adoption by their members, respectively, of a standard quick acting, quick detachable, demountable, or universal rim, which will be satisfactory to car and tire makers alike.

PREPARING FOR A BIG CAMPAIGN

Detroit's "All-Star" Combination Announces Its New Car—Acquires Northern Plants and License.

The opening gun of the selling campaign of the Everitt-Metzger-Flanders Co., of Detroit, has been fired in the issuance of a broadside of information concerning the car which the much hyphenated concern is putting out and a statement of the company's organization and resources, all of such a nature as to give assurance of the large place which it is bound to occupy in the field in the very near future.

By the acquisition of the two plants of the Northern Motor Car Co. in addition to the Wayne plant, the manufacturing facilities of the company have been expanded to a point where the expected 12,000 car production for the coming year is in the range of easy accomplishment. The Northern factory at Port Huron, Mich., is to be used chiefly for the making of parts and axles, while the cars in their final form will emerge from the former Wayne plant.

Agency arrangements for the new $1,200 four cylinder, five-passenger car, which is styled the E-M-F "30," are in the hands of William E. Metzger, the secretary and sales manager. As sales manager of the Cadillac Motor Car Co. from its start, Metzger has had an experience which very few men in the trade can begin to equal, and he is widely known throughout the length and breadth of the country.

The production end is correspondingly strong, being in charge of General Manager Walter E. Flanders, who is credited with a great share of the marvels wrought in production system at the Ford Motor Co., which concern he left a few months ago to join the new enterprise. Backing Flanders are Factory Manager Thomas Walburn and General Superintendent Max Wallering, while Chief Engineer William E. Kelly has been in the automobile business as a designer from its infancy.

The heavy duties of the general business management of the company devolve on Byron F. Everitt, the president, who as the organizer and moving spirit was responsible for the selection of an "all-star" caste. Supporting Everitt in the matter of financial resources are J. B. Book, Charles L. Palms, William T. Barbour, and Charles D. Bennett, these men with Everitt, Metzger and Flanders, forming the board of directors. The advertising and publicity is in the hands of E. Le Roy Pelletier, whose connection with the Ford Co. in the same capacity, established recognition of his ability.

The Selden license rights of the Northern Motor Car Co. will make the company a "licensed" concern, so that the cars will be available to "licensed" agents.

FRANKLIN Automobiles

Franklin air-cooling proves up on the road. See what it did in the Glidden tour.

With all the climbing and hard pulling and low-gear work no Franklin ever had to stop to cool off. Nearly every water-cooled automobile had to. Some had to put in water every 20 miles. The Franklin towed bigger cars up one steep hill. The *Horseless Age* said the Franklin made better average time than some competitors with twice the horsepower. The only penalty against any Franklin was for broken springs. Our springs were not wound as others were; and two Franklins came through with perfect scores. The water-coolers declared they didn't believe the Franklin could do it.

No one who knows the facts ever asks honestly if Franklin air-cooling cools, and it makes the whole automobile simpler and stronger, more powerful in proportion to its weight, and more economical than is possible with a water-cooled motor.

The Franklin Model H Touring-car with its 42 horsepower and six cylinders weighs under 2,500 pounds. The majority of six-cylinder automobiles weigh from 3,500 to 4,000 pounds. Type H will average 14 miles on a gallon of gasoline, carrying seven passengers. And it will go 55 miles an hour if you want it to. Not catalogue speed; real speed.

Type H is the easiest riding and smoothest-working automobile in the world. You can't hear nor feel the engine. It is as handy and easy to manage as any little runabout. And there isn't a more durable automobile in existence.

The Franklin Type D five-passenger automobile weighs under 2,200 pounds. Other five-passenger automobiles average a third heavier. The Type G family touring-car weighs 1,600 pounds.

You have no plumbing system to lug nor bother with in a Franklin; no water to leak nor boil, nor freeze in winter. You can use a Franklin any minute in the year.

The Franklin concentric valve and dome-head cylinder get 25 per cent. more power out of the fuel. The Franklin auxiliary exhaust discharges 60 per cent. of the dead combustion-heat immediately after the explosion, without carrying it back through the cylinder.

These are the two most important inventions in automobile engineering. No automobile but a Franklin has anything like these features, nor any means of getting their results.

Franklins have always been air-cooled—for seven years. And 6,000 air-cooled Franklins are now in daily use.

An automoblie is as good as it does. Put any Franklin to this test.

Unsatisfactory End of Glidden Tour.

It was a long, hard trip for the sake of a squabble at the end.

Whether there is any longer a good reason for running the Glidden tour until all perfect scores but one are marred or broken is still in doubt. The results this year almost make the judicious yearn for a tour in which every one might finish with a perfect score and barrels of honor.

Just as the affair draws to a close, an observer with more fidelity to the rules than to ethics of the occasion, quietly marks his little report card, adding some three minutes to his car's schedule without the driver knowing that he has done so. Oppressed with a sense of his official responsibilities he keeps his lips tight as the driver checks in on the regular schedule, which according to the observer's calculations is three minutes too soon. The result points to the fact that there is great luck in getting an observer who can be strict and impartial and yet exercise common sense and justice.

A protest was filed, urging that a penalty should be imposed against the car in accordance with the rules. A natural action, indeed, but how idle to appeal to the rules as rigid guides. There was but one rule in the lot that could be regarded as fixed and certain. Again let us dwell on it as a masterpiece of autocracy and latitude in sport:

"The Chairman of the Touring Board reserves the right to alter or amend, suspend, or repeal these rules from time to time, up to and including the end of the tour and final award, as may in his judgment be deemed expedient."

If the cause of justice was served in suspending the action of the other rules so far as the technical penalty of an otherwise perfect score team is concerned, so much the better, but a "beneficent despotism" which makes a contest like the Glidden tour simply a "blind run" with one man the Only Rule in the ultimate, should never be permitted to exist again.

Advantages of the Two-Cycle Motor.

It never ceases to be a source of wonder to one not a gas engine designer by profession that the introduction of the two-cycle type of motor has not been more extensive among automobile constructors. Its freedom from mechanical complication, the simplicity as well as the small number of its moving parts, its relatively low cost of construction are sterling recommendations which should weigh very heavily in its favor when the specifications of a new model are under consideration. With the alluring possibilities of multiple production, the problem of repairing the two-cycle motor becomes merely one of the substitution of parts—an operation which, save in the case of crank shaft bearings, requires practically no hard work or other fitting. Its low cost of upkeep therefore, should appeal very strongly to the purchaser.

Over against its advantages may be mentioned its reputed unreliability, due principally to the erratic performance of certain very small motors which have been carelessly produced for motor boat propulsion; its unresponsiveness to throttle control, and its relatively low fuel economy. Of the erroneous impression which a few unhappy experiments have caused to be applied in many instances to the entire class, it need only be mentioned that for every unsuccessful motor of this type there are many which are sufficiently sucessful to go thumping on, day after day, in the service of fishermen and other users of small utility craft under conditions which probably are much worse than those met with in automobile service. As a matter of fact, experience with the few makes of automobile motor in which the two-stroke cycle is employed, has fully justified its use. The apparent instability of the average motor of this class under conditions of varying load and throttle opening, is one which may be largely overcome by good design and a better understanding of the problem of carburation than has been current hitherto. As for fuel economy, its importance must be considered insignificant, except in motors of more than moderate power. For the purposes of the ordinary touring car, it is not of noteworthy magnitude.

In the paper on two-cycle design, printed elsewhere in this issue, the student of the gas engine may find considerable valuable data. The method of distributing the gases in the two and four stroke types is so radically different that it is small wonder the pioneers in this field should have had their full share of trouble in perfecting a motor having the desired flexibility. The chief difficulty arises in the proper proportioning and positioning of the ports. The slightest deviation from the proper location or the smallest fraction of a square inch variation in area from the standard may be responsible for tremendous differences in the operation of two motors built after the same designs and apparently duplicates in every respect. The general principles to be followed in laying out a motor of this class are clearly defined in this connection, and in unmistakable terms, free from the confusing methematics which usually enshrouds pure theory. For it is to be remembered that the facts set down result from the conclusions of actual practice rather than of untried ideas.

The fascination of the two-stroke motor —its simplicity—tends to the conclusion that it must be as simple to design and build as it is to assemble and operate. Herein lies a considerable error, and a probable explanation of the discouraging results which have been obtained by constructors who have not been eminently successful in this field. The fact is the two-stroke cycle motor is difficult to build with any degree of success, unless precautions are taken to have all parts made to closest gauge, and of the right materials. On this account the

Digitized by Google

type is not to be regarded as cheap to build from the standpoint of first cost. Once the design is carried through properly, however, and the arrangements for accurate production on a large scale perfected, it would seem that the investment should prove an extraordinarily profitable one.

The Value of Motor Parkways.

With the completion of the first section of the Long Island Motor Parkway, the old enthusiasm at the notion of having a highway exclusively of and for motoring interests, struggles bravely to the fore again. The delights of possession which mere membership in the fraternity afford in this connection tend to crowd out soberer reflection as to the immensity of the undertaking, and the number of obstacles which must be overcome in bringing it to pass. The probable success of this, America's first motor highway, also is likely to stimulate the rehabilitation of several other schemes of a like nature which at one time or another have obtained a measure of public notice.

At the same time, it is well not to overestimate the probable value of such courses nor to speculate too freely on the possibility of a general extension of their use. For the purposes of international and national competitions, of experimental tests of various sorts, and of pleasure runs, such facilities are of very great importance, especially when brought within convenient reach of a great city. The exclusive motor highway is useful to this extent: that it removes from the common public roads such competitive events as might cause inconvenience and danger to the ordinary users of those thoroughfares; that it ensures the maintenance of a proper road surface, free from the desructive effects of the hoofs of animals; and that in the absence of uniformly good roads, it provides a limited area of nearly perfect footing for the machine. The common highway must still retain its own peculiar function in the community, however, and it is extremely doubtful whether any chain of special roads adapted to interurban travel on the horseless plan ever will be realized. In catering to the needs of a somewhat limited class it would even appear that the realization of this vision would be counter to the best interests of commercial prosperity. It would mean a cessation of the interest of the motoring contingent in the good roads movement, so far as affected by such enterprises.

England's great motordrome at Brooklands, though built as a race track rather than a parkway, is based upon the same idea as has been the moving course in the Long Island instance. The proposed courses in Germany and France, the latter of which just now is being freely agitated, also have a similar purpose. Probably the not distant future will see several other undertakings of the same nature, all on a large scale, and formed with the purpose of providing motorists with a suitable opportunity for the unrestricted pursuit of the pastime of fast driving. As commercial ventures, it is likely that they will repay the investor more or less in proportion to their proximity to great cities. Certainly, the appreciating realty values of such locations is destined to form a welcome security for the money sunk in them. The idea that such undertakings ever will be expanded into an independent highway system, however, is not a wholesome one to cherish.

Dealing with a Needless Offense.

It is to be observed that tardiness in coming into an appreciation of the common welfare of others, invariably results unpleasantly for the offender of the public In the case of the heedless motorist, oppressive legislation has more than once been threatened, and occasionally brought into effect. The flagrant abuse of the speeding capabilities of the automobile, however, is by no means the only disagreeable result of placing the machine in the hands of reckless and thoughtless persons. That the Park Commission of New York City is perfectly justified in ruling out of its precincts all motor cars which give forth offensive vapors is not to be denied. Such a measure, applied to the whole city has been threatened already, and avoided, largely, it is to be supposed, through the indolence or indifference of the aldermen. That it may follow this, however, unless owners and drivers are brought to a realization of the seriousness of the smoke nuisance, is a natural conclusion. That the companies operating vehicles for hire are alleged to be the worst offenders in this respect, should tend to quell the resentment of the private owner against what he otherwise might regard as an added invasion of his liberty. The smoke nuisance is a needless offense. Its suppression may be brought about either through a popular appreciation of this fact among users, or by more irksome means. It is to be hoped that this latest park ruling may serve as a timely warning and forestall the passage of more generally restrictive measures.

COMING EVENTS

August 1, New London, Conn.—Hill climbing contest on Town hill.

August 1, Wildwood, N. J.—Motor Club of Wildwood's annual mid-summer race meet on Central avenue boulevard.

Sept. 1, 2, 3, and 4, Chicago, Ill.—Chicago Motor Club's postponed 1,000-mile reliability run.

September 7, Lowell, Mass.—Lowell Automobile Club's 200 miles road race, on Merrimac Valley boulevard.

September 7, Columbus, Ohio—Columbus Motor Club's 24 hours endurance race at Columbus driving park track.

November 26, Savannah, Ga.—Automobile Club of America's (New York), 400 miles outlaw race for foreign cars.

December 31-January 7, New York City—American Motor Car Manufacturers' Association's annual show in Grand Central Palace.

January 16-23, New York City—Association of Licensed Automobile Manufacturers' annual show in Madison Square Garden.

It would be interesting to follow out the reasoning which construes the act of warning people against possible arrest for violation of law as one calling for suppression by the police. Some "Good Samaritan," it appears, has been distributing cards at the St. George terminus of the Staten Island ferry warning automobilists to watch out for plain clothes men of the police force into whose hands they might fall through "letting her out" on the island streets and roads. When the fact became known the police were ordered to look after him. It does look as if the man who does anything to assist in obtaining respect for the laws is doing in his own way, and not in an illegal way either, exactly what the police are employed and paid for doing. To prevent law breaking is as desirable and as commendable as to make arrests and secure conviction when the law is broken. In England, where the question already has been thrashed out pretty thoroughly in establishing the status of the "scouts" regularly maintained for a similar purpose by one or another of the motoring organizations, it is interesting to observe that this view has been recognized by courts of law.

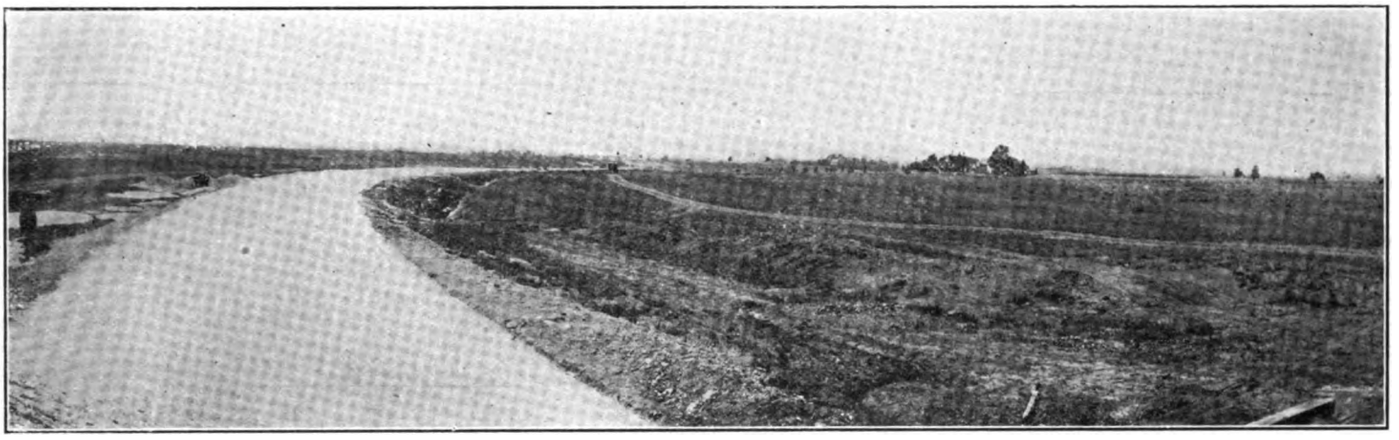
PROGRESS ON MOTOR PARKWAY

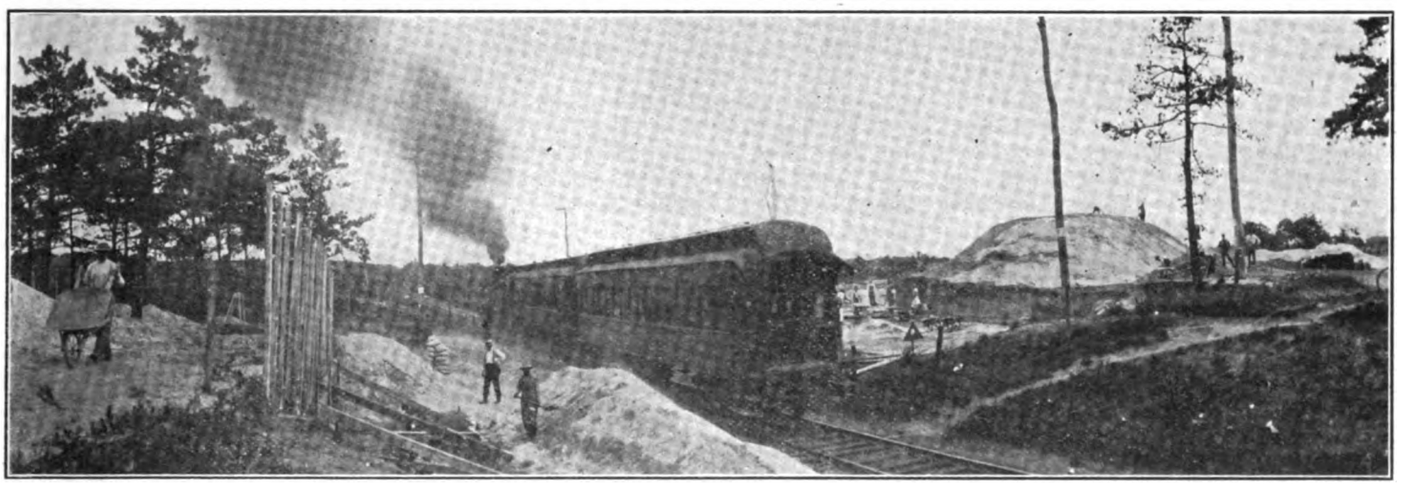
Five-Mile Stretch of the Road Completed —Will Constitute Part of Course for Vanderbilt Cup Race.

While the Long Island Motor Parkway project has been kept very quiet since the day of the opening celebration last June—on which occasion General Manager A. R. Pardington, in the absence of President William K. Vanderbilt, Jr., turned the first spadeful of earth—the work of road building has been progressing rapidly and under favorable conditions.



An enormous amount of work was encountered by the promoters of the enterprise, who found that before the actual road building could be commenced there was a mass of executive detail which must needs be taken care of.

A portion of the first section of the road has been completed—a stretch about five miles long, located south of the town of Hicksville. The completed portion is approximately one-half of the section, which in its entirety consists of that part of the Parkway running from a point directly north of Farmingdale to about one mile east of Garden City. It is this section of the road which has been included in the course selected for the Vanderbilt cup race of 1908; and as its length is about 11 miles it contributes slightly more than one-third of the entire cup course. While but a portion of the section is finished at this time, so much has been accomplished on the unfinished part that there is not the least question but that the terms of the contract, which call for the entire section to be finished by October 1st, will be fulfilled.



The accompanying illustrations show the completed roadway and give an idea of the immensity of the undertaking. Not only was it necessary to build a road through virgin country, but the construction of it, for its intended purpose, presented problems which had not previously been encountered, as no similar project had been attempted. Roughly speaking, the plan of the construction of the parkway is the same as is followed in railroad building; that is to say, sharp curves have been eliminated, grades, so far as it was possible, have been levelled, and when levelling could not be accomplished, slopes of a long, gradual degree have been arranged in preference to short, but severe hills. Of prime importance to motorists was the decision that the parkway should be free of grade crossings.

Obviously this constructive plan necessitated many "cuts" and "fills" and the material for the latter largely was supplied by the material taken from the former. To avoid grade crossings it was necessary to build bridges above the tracks. On either side of the railroad right of way cement foundations were erected to support these viaducts, the approaches to which were made gradual by filling in the land for a considerable distance. That these "fills" are considerable is demonstrated by the illustration which shows the distance between the railroad track and the knoll on the right. The intervening space will be filled in solidly, the roadway made on top of the "fill" which will be of a height sufficient to carry it a few feet above the top of a train.

With the opening of the first section comes renewed interest in the enterprise and with the opening is dispelled all doubts as to the future of the parkway.

VANDERBILT CUP RACE PLANS

October 24th the Probable Date, but not officially Announced — Elimination Contest Carded for October 10th.

Doubtless there will be a race for the Vanderbilt cup this year, and what is more to the point, it will likely take place on Long Island on the morning of October 24, although no official announcement to that effect has been made. It has been announced that the elimination race to decide the American team will occur on the morning of October 10th.

The news of the date of the Vanderbilt cup race came out this week only through the fact that A. R. Pardington, vice-president and general manager of the Long Island Motor Parkway, Inc., had applied to the Board of Supervisors of Nassau county for permission to use the roads of that county for the elimination race on October 10th, between the hours of 5 a. m. and 10 a. m., and for the race proper on October 24th, between the hours of 5 a. m. and 3 p. m. A public hearing will be given on the petition August 3d, at 10 a. m.

As no official announcement has yet been made by the American Automobile Association the Motor World sought to verify the news of the application for permission to close the roads on that date. When seen in his office Secretary Elliott would neither affirm nor deny the facts. That an official statement will be made by the American Automobile Association next week was all he would commit himself to say.

Later a statement was sent out through the publicity department of the association to the effect that another car has been formally entered in the Vanderbile cup race, making the third entry that has been received by the cup commission. The date of the elimination race was announced as October 10th.

The latest candidate for the American team is a special Chalmers-Detroit, 50 horsepower stock car, the entry being made by J. S. Harrington, of Worcester, through the Worcester Automobile Club. Oliver Light is named as the driver.

The other entrants who have deposited fees are Robert Graves, who enters a Mercedes in the race proper, and W. W. Burke, who has entered a Mora for the elimination. The Mercedes car will be driven by Lautenschlager, who won the Grand Prix recently. The driver of the Mora car has not been named.

The course for this year's Vanderbilt cup race, according to the application of Vice-President Pardington, will embrace the following circuit: Beginning at the Round Swamp road at or near the juncture with a road known as the Manetto Hill road to Plainview, thence on a straight road to Woodbury, and east along the Woodbury road to a point or juncture of the Woodbury road with the Jericho turnpike, over the Jericho turnpike west to Jericho village, thence south from Jericho village on the Massepequa-Oyster Bay road to its point of juncture with the Jericho turnpike, thence west over the Jericho turnpike to the old Westbury road, thence south to the Old Country road and easterly along the Old Country road to Merrick or Whale Neck avenue, thence along Merrick avenue to a point about 400 feet north of the Central Branch of the Long Island Railroad to the roadway of the Long Island Motor parkway. About ten miles of the parkway is to be used and the official grandstand will be located on this stretch.

Sioux City Sees Good Racing.

Barney Oldfield and Charles Soules were the attraction at the meet held by the Sioux City (Ia.) Automobile Club at that city on July 18th, but although the track was in good shape no records were at any time in danger. Soules is now Oldfield's racing partner and the pair were able to make a good race in their three miles match. Soules got the pole at the start and maintained a lead of a length until the mile where Oldfield gradually closed up the gap and won out in a grandstand finish by a half length.

In their mile record trials Oldfield covered the lap in 1:04⅕, and Soules was timed in 1:07⅖. James Graves, an 18-year-old lad, hailing from Wayne, Neb., won more plaudits than did the professionals. He won the 25 miles for fully equipped touring cars, the three-miles free-for-all and the novelty. The two runabout events went to Walter Gnehm and Eugene Gnehm.

Wildwood's Midsummer Racing Program

Saturday next, August 1st, will be the date of the annual midsummer race meet conducted by the Motor Club of Wildwood, on the level Central avenue boulevard, that city. Ten events have been carded, as follows: Gasolene cars selling under $1,250, six cylinder cars, free-for-all, gasolene cars between $3,001 and $4,000, four cylinder gasolene cars over $4,000; free-for-all kilometre time trials; steam cars only; mile time trials, free-for-all; stock touring cars carrying four passengers.

New London Cards a Hill Climb.

New London, Conn., intends to place itself on the automobile map by holding a hill climbing contest in that city on Saturday afternoon next, August 1st. The events will be held on Town hill. Five events are on the card, as follows, according to price classification: Under $1,000, under $2,000, under $3,000, under $4,000, and a free-for all.

The Selma Automobile Club has been organized in Selma, Ala., with the following officers: President, Huston Armstrong; vice-president, G. S. Armstrong; secretary, James Kenan; treasurer, H. A. Denton.

GERMANY CLAIMS THE "RACE"

Protos Car, First to Arrive at Paris, Protests Its Handicap—The Thomas Delayed on Final Stage.

The railway-steamship-and-otherwise aided German Protos car, having arrived in Paris ahead of the other competitors in the New York to Paris "race," the Zeitung am Mittag, the Berlin newspaper which backed that car, has promptly claimed the race as being won, protesting against the allowance of 30 days to the American Thomas car as "an impossible sporting procedure." The German car arrived at the French capital at 6:15 p. m., Sunday, 26th inst. Thus it wins the trophy offered by Grand Duke Vladimir, of Russia, to the car first completing the big journey. Lieutenant Koeppen, the driver of the car, was lionized upon his arrival, and none were more hearty in their congratulations than the American residents. The Protos car completed its trip on the 166th day after the start from New York. On that day the American car reached Koenigsburg, 1,051 miles from Paris, at 9.40 a. m. The Italian Zust car had not been reported since four days previous, when it was at Tomsk, Siberia, 5,340 miles from Paris. The Italian car has an allowance of 15 days against the Protos.

It is not expected that the Thomas car will arrive in Paris until this (Thursday) evening. The American car has been beset by ill fortune during the later period of its running, and Schuster and Miller were again the victims of disappointment yesterday when a coupling-shaft gave out 12 miles from Hanover, which city they left at 3 a. m., expecting to arrive at the French capital by evening. For 16 hours they worked under a wayside apple tree and it was 8 o'clock in the evening before they had completed the repair.

Even at the early hour when the Americans set out from Hanover, they were piloted out of that city by a car that had come all the way from Dortmund to show them the way. There were several ladies in the pilot car, and they appeared delighted by their experience. They set a stiff pace, and almost brought the Americans to grief. The fog still hung low, and a number of farm wagons were met on their way to market, with the drivers asleep in their seats, paying no attention to the course of their teams. It was only by good luck that several collisions were narrowly averted.

Desiring to have women automobilists take an interest in club life the Minneapolis Automobile Club has altered their constitution so that the fair sex may join. The $25 initiation fee will be waived when the applicant is a woman.

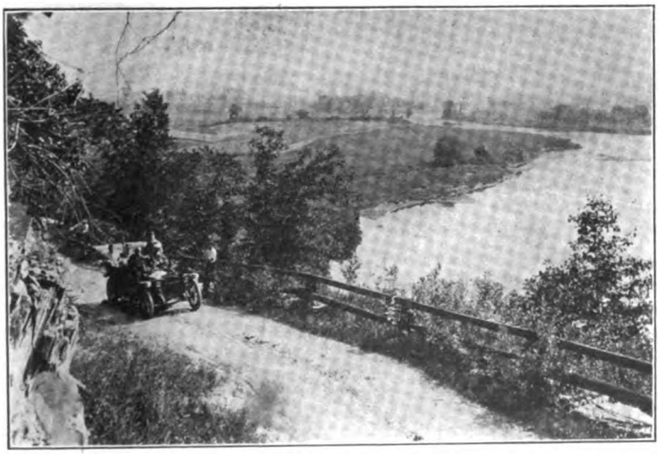
GLIDDEN'S CUP IS RETURNED

Pierce Refuses It Because of Dispute—Clifton's Pierce Wins Hower Trophy—Gleanings of the Tour.

Somehow the Glidden tour did not end nicely at all. There was not the hilarity to its conclusion that has marked similar events in the past, and a row over whether one or three teams in close contest for the trophy should or should not be penalized brought the thing to an unsatisfactory conclusion. As matters stand now, the Glidden Trophy is in the hands of the touring board of the A. A. A., because the George N. Pierce Co. would not accept it under circumstances in which their right to it might be under the shadow of a doubt.



The competing cars arrived in Saratoga, N. Y., early on last Thursday afternoon, and it was thought that the Buffalo team, consisting of three Pierce Great Arrow cars, the Columbus team, consisting of three Peerless cars, and the Chicago team, composed of two Haynes cars and an Olds, were in a three-cornered tie for the trophy. However, the driver of the Olds in the Chicago team, Andrew Auble, had some days before announced his intention of quitting at Saratoga, whether his car was in the tie or not, so that it looked like a run-off between the Pierce and the Peerless teams.

Nevertheless, before evening it was discovered that the observer on J. W. Maguire's Pierce car, of the Buffalo team, had by his record card made the car appear guilty of having come in three minutes before it should. Allowing the two minutes leeway permitted by the rules, the car would thus be one minute off its proper schedule, which would impose a penalty of one point against the car and one-third of a point against the team to which it belonged. Despite the observer's report the car and team were given perfect scores.

At the evening meeting of the contestants, Charles Burman, representing the Peerless team, filed a protest with Chairman Hower to the effect that in accordance with the observer's report and the published rules concerning penalizations for checking in ahead of time, the Pierce team should be penalized. The matter was gone into with detail and it transpired that the observer's action in adding three minutes to the running time of the Pierce was due to the fact that the car stopped for a brief halt on the way into Saratoga to take off the tire chains. Since the rules provided that all time spent working on tires, with the engine running and no other repairs being made, should be added to the running time allowed, the observer added the time spent in removing the chains, making a record to that effect on his card. Maguire, on the other hand, had not thought of it as being work on the tires themselves and it did not occur to him that the observer had made any additions to his running time. The observer vouchsafing no information or comment as Maguire drove confidently in on his regular schedule, the car arrived at the checking station three minutes before the time that the observer's calculations would have

SARATOGA'S WELCOME AT TERMINATION OF THE TOUR

ALONG THE WINDINGS OF WHITE RIVER, VERMONT

VIEW BETWEEN RANGELEY LAKES AND POLAND SPRINGS

Digitized by Google

set as correct. When Maguire was called upon to sign the observer's record he protested that it was wrong, and that the time consumed in taking off the chains had not even been as much as three minutes.

The facts influenced giving the Pierce team a perfect score, and, when the Peerless protest was presented to Chairman Hower he turned it over to the "committee," composed of Buffalo men, for decision in secret conference. He did not wish to shoulder alone the responsibility for overruling the Peerless protest, and it was left to his "committee" to turn it down on the ground that the observer made a mistake.

JUST GETTING ACQUAINTED.

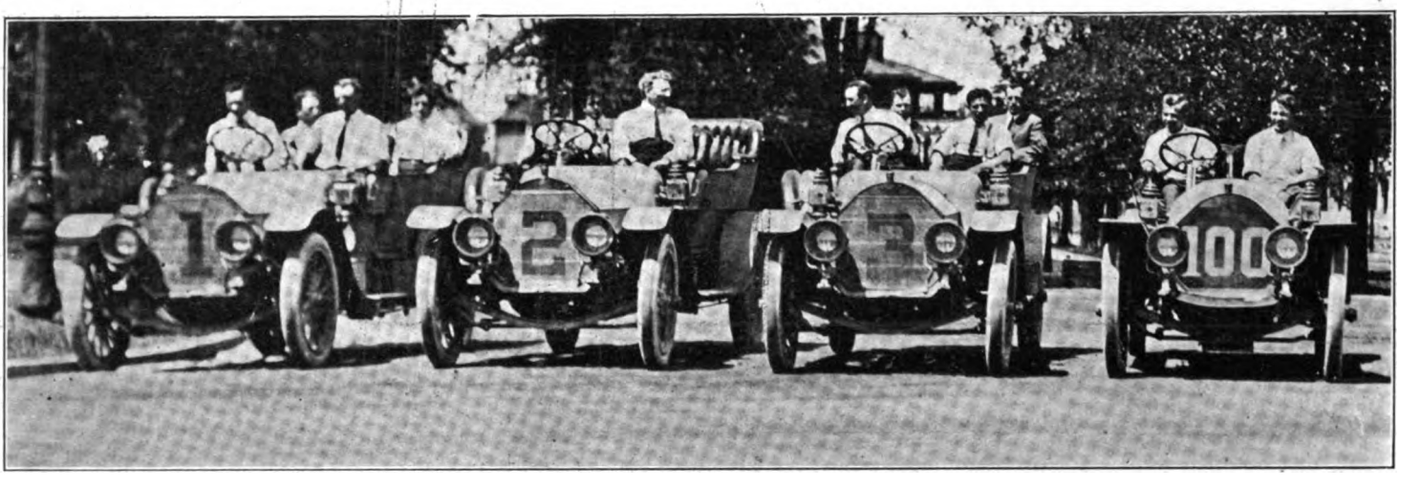
Feeling being rather high, the Peerless people declared that if the rules as set down were to be administered with so much leniency on certain occasions and to be enforced with rigidity in others, their cars would not compete in a run-off for the cup, and their withdrawal was announced. Henry May, vice-president of the George N. Pierce Co., being in Saratoga at the close of the run, and hearing of the disallowed protest of the Peerless team, directed the Great Arrow team to drive to the starting line the next day and then to refuse to cross the line if the Peerless team did not appear for the run-off.

The latter had not weakened in their position over night and did not show up, whereupon May wrote Chairman Hower, stating that inasmuch as no competitors had appeared for the run-off, he had ordered his team not to cross the starting line, as it was not the wish of the Pierce company to win the trophy on a fluke. This sportsmanlike action was the subject of very general approval and quite offset such doubts as had been cast on the Pierce honors because of the technical misunderstanding on time calculations. Its practical effect was to leave all three teams tied, according to the official records.

Whatever honors the Pierce cars may have relinquished in the Glidden contest were compensated for in the Hower competition. Five cars in the Hower class finished at Saratoga with perfect scores, including two Pierce Arrows, two Stoddard-Daytons and a Premier. It took four more days of road work to find the two Pierce cars left alone in the running. The run-off was from Saratoga to Syracuse, to Buffalo, to Cambridge Springs, to Pittsburg, all on a very fast schedule. The trip from Cambridge Springs to Pittsburg ditched the Premier, while the two Stoddard-Daytons were withdrawn at Pittsburg in the evening. Next day Clifton's Pierce, by consent, ran alone to Bedford Springs, thus winning the trophy.

OVERLAND, WITH PERFECT SCORE, HALTS TO HELP

Of the cars in the Glidden competition to finish at Saratoga with perfect individual scores, there were fourteen in addition to those on the three teams in the tie. These included the two Stevens-Duryeas, which were running for certificates only, and two Franklins, two Studebakers, and one each Premier, Thomas, Gaeth, Rainier, Oakland, Marmon, Garford and Reo, making in all a total of 23, of the 32 Glidden class cars, and 5 of the 14 Hower class, that made the whole 1,700 miles without a penalty.



Gleanings from the Glidden Tour.

There are those persons who like motoring to such a fanatical degree that naught satisfies them until they can go off on a grand two weeks of more or less hardship—climb half a dozen ranges of picturesque though rough mountains, spend a lot of money, break a few bones, shake loose a few ribs which subsequently lodge in their livers, and likewise jar out all the fillings in their teeth, which are swallowed even as pills, while bumping over a long and progressive series of water-breakers. There are those persons who do such things because they are paid for it and would lose their positions if they declined, namely the drivers and mechanicians. Then there are those who go as war correspondents, partly for the joy there is in it and withal using their paper as an excuse and means of defraying expenses, in order that said paper may get the latest and best war news of the great tour, fresh from the front.

I was one of the latter—right there on the firing line with the other thirty-odd high tension news artists who wore dainty blue badges with pretty fobs labelled "Press." We were the busiest passengers on the tour, too, for we had to work at the end of the day and scrap to get our stuff over hot wires while the rest of the crowd sought readjustment of their systems in slumber. And let no one deem it a simple matter to separate fact and fancy and flash the "news" to a listless world when your bones are bent with much jostling and your dusty eyes cry for sleep.

The Hower Tour set out from Buffalo, N. Y., on July 9th, to demonstrate that Hower's Pierce team could lick any other team—or so the early kickers had it—for was not Frank B. Hower riding right at

PIERCE TEAM AND RUNABOUT WHICH MADE PERFECT SCORES

the head of the procession in a car of that make, closely followed by five other cars of the same make?

Clubs? That's so. The fifth annual reliability and endurance contest of the American Automobile Association, for the Glidden trophy was to have been a club affair. For the "club" part of the affair it was more or less a farce. There were three Pierce cars forming a team, running under the emblem of the Buffalo Automobile Club; there were three Peerless entries representing the hitherto unknown Columbus Automobile Club; there were three Marmons flying the Bay State A. C. streamers; three Studebakers said they were the Rochester A. C., and a trio of Garfords constituted Cleveland's representation. In other words, automobile clubs had about nothing to do with the whole affair, and the contest was wholly a manufacturers' tour. Fancy Mrs. Cuneo, she who is a class by herself, a resident of Richmond Hill, L. I., driving as one of the Chicago Club—a club in which she was never interested to any extent. Think of the honor for this club to have Mrs. Cuneo on its team. If the three A.'s annual contest is to be an out-and out manufacturers' event, why run teams under the guise of "clubs," borrowing the names of legitimately organized or other automobile organizations?

MRS. JOAN CUNEO, RAINIER.

The writer rode in that car known as the Moline roadster, driven by that prince, Neil Vandervoort. This was the only car in the run which did not burn gasolene. Instead, it burned "gaso-moline." The latter remarkable substance was used both as a fuel and lubricant, answering equally well for each purpose. Some said that it was also put into the grease cups, but this was not so. In this car, I had a highly adventuresome trip, notably on one occasion, when at Blairsville, Pa., a stuffed effigy of a man was suddenly hurled in front of the machine. The dummy struck the front of the car and hung on the springs. The crowd laughed and considered it a great joke. They asked for their baby back, but Vandervoort refused to give it up, fearing that they might repeat the trick and cause an accident. So we carried the dead man up into the mountains and threw it away.

Perhaps our most surprising adventure though, occurred up in Maine, during the latter part of the trip, at Mexico, 50 miles

PERFECT SCORE GARFORD, NO. 30

Digitized by Google

from Rangeley. A porcupine—a Mexican porcupine, of course, darted out from the pine woods with his quills standing on end and we ran over the cute little fellow. When we stopped, we found that his spicules had punctured a right front shoe and made it go flat. Think of that! Nevertheless, Neil Vandervoort made the gamiest run of the whole contest, making up two days' lost time between Harrisburg and Boston, and running from there on, under schedule. Meanwhile, his eye was in very bad condition, requiring Dr. Hoag's attention.

PERFECT SCORE CHICAGO TEAM TWO HAYNES CARS AND AN OLDSMOBILE

The first thing on the Hower tour that really "got the tourists' goat, was that range of Allegheny mountains and their neighbors, the Blue Ridge, Scrub and Laurel. We crossed them last year on the tour and this season they seemed even worse than before. Those same old waterbreaks were there, more ghastly that ever—thousands of 'em, as we counted—and they made us feel like pulp long before the summits of those tough mountains were crossed. And yet, the cars stood the siege far better than last year and tire trouble was not nearly so plentiful. We tourists felt the effects of the bumping though, and the constant jouncing and vibration was no joke. Why, did not Mrs. Berwick, who rode with Mrs. Cuneo, pick some milkweeds at the foot of the Scrub Range mountains and were they not churned to buttercups by the time those hills were surmounted?

Of course the tour was not all hardship and bumps—not by a long sight. There was plenty of fun, fast and furious. Some of us who rode in non-contesting cars would stop at intervals and kid the girls along the route. At the different night stops we often found plenty else to amuse us. Harrisburg and Philadelphia tendered us smokers and when we reached Boston, the Bay State Club treated us royally. On Saturday we were given a clambake at Paragon Park, and we had great doings. When the banquet was over and the speeches by the mayor and others finished, we went out and paraded around lock-step for a while, wearing ten-cent "Merry Widow" hats. Then we started in to see the shows systematically. Half a hundred of the more foolish ones half killed themselves on the "human roulette wheel," which is nearly as bad as crossing the Allegheny mountains, or partook of that form of amusement known as "bumping the bumps, which vividly recalled the experiences of a few days before. Ultimately we adjourned to a "high class" vaudeville show. The seats of the front row, which were nailed down about eight feet from the stage (to allow some room for an orchestra, perhaps), were not close enough to the footlights to suit the eager tourists. Therefore we pulled up said rows of seats by the roots and shoved them forward until all got a better view. It must have taken the proprietor two days to straighten them back into place again.

LORING WAGNER, HAYNES, WITH JAPANESE COUNT AS PASSENGER

Sunday at Boston, Mayor Hibbard turned over one of the municipal steamers to take us down the bay for a fine sail, shipping plenty of both kinds of refreshments along with us. The boat, by the way, was a little jest in itself, for it proved to be the Monitor, which is used to transport the local prisoners to their "hotels." For awhile we busied ourselves trying to lock each other into the little compartments used as cells.

Milton Lusk, at the keyboard of the Gabriel horn-organ car, provided endless amusement, for he played almost every tune we had ever heard and many that we had not. At each place we would stop for the night, a crowd would pile into the car and tear around singing Glidden tour songs to his accompaniment. Some of those classics which we yelled with lusty lungs were wild indeed, such as "Tour Days," to the air of "School Days"; also that one to the tune of "The Garden of Love," beginning "Won't someone kindly tell me, won't Hower answer why——"; or another, "Listen here, Hower dear, I'm afraid to check in after dark."

At Milford, Pa., there was no end of kicking about hotel accommodations. Many of us went up to our rooms to retire that night and found our beds already occupied by others—about three to a bed. At this place they gave us most any old thing to eat—old shoes fried, stewed blankets, blanc mange made from rubber tires, and things.

It was when we departed from this spot that one of the most novel ideas of the whole tour sprang up. A publicity man and a playwright, got their heads together with a few of their comrades and painted pretty signs to post on trees along the route. Such inscriptions as: "Hurlburt spare this tree!" "I assume you are all present" (Hower's favorite phrase when addressing a meeting), "Ain't it awful, Mabel?" and a few more.

One of the most ludicrous was posted on a tumble-down dirty little hovel, inhabited by Italian laborers, and read: "A bath with every room." This appealed to some of us who had experienced the no-bath inconvenience, notably at the Avondale, where some of us were lodged in Bedford Springs—a hostelry which possessed no bathroom!

The observers were a quaint set. "Shock observers," they were called, and what some of them did not know about cars, was well worth knowing. At the start the observer appointed by Mrs. Cuneo turned out

Digitized by Google

to be a young newspaper man who had never ridden in a car. When he was assigned to A. L. Kull's Gyroscope, the driver had all sorts of fun with him. This car was known as "Kull's Giraffescope—eats leaves off trees," and when the machine would stop, either to chew foliage or on account of tire trouble, the observer never knew whether or not the engine was going—an important detail, as extra time was allowed for tire changing, while an engine was kept in motion.

"Is that motor running now?" the observer would blandly inquire. And Kull would reply: "Why feel the radiator; it's hot!" If the radiator was hot, the observist took it for granted that the engine was running. It was most interesting to hear this young chap naively relate all this and tell how Kull used "magic powder" to make his auto go. When the friction drive would get stopped with oil, so that the fly wheel and transmission wheel would slip, the driver would take a handful of "magic powder" from the middle of the road and throw it between the friction wheels. As a result, the machine would jump more like a kangaroo than a giraffe, and sometimes even stall the motor.

The observer who attracted the most attention was Kenneth R. Otis, who weighed 325 pounds. He was a handicap to any car that carried him and he knew it and did not care either. It was while transporting him across the White mountains that one of the Marmon cars crushed a wheel.

One of the Haynes cars carried a young Japanese, Mr. T. Ninagawa, who for publicity purposes was said to be a count, sent here by the Mikado to study motor car manufacture. This, however, he personally denied. I asked Ninagawa, who speaks very good English, to write on paper what he thought of the tour. What he quaintly wrote is printed here, as he penned it, merely to give his own views in his own characteristic fashion, and in no sense of ridicule.

"Perhaps one of the most serious and reliability testing cars is the Glidden Tour. I have been studying the automobile trade last three years and I feel I want to take like this reliability touring contest. So I am glad that I could get a seat in the Haynes, which is one of the best make.

"The car which takes the reliability contest proves it quality, even if it run only one day. I mean that a car which contests in the Tour only one day is better testing in the round city or town a week or fortnight.

"I am very surprised that American roads is most nearly perfect in condition. Anyway, I believe that American made is further more better than high priced European made.—T. Ninagawa."

Scenically, the tour this year was far and away ahead of that of 1907. A more varied panorama of beautiful country could not have been arranged. For this, the "Pathfinders," L. M. Bradley, Lai Lewis and others, acting under Mr. Hower's instructions, are to be thanked, in this respect, mountains in Pennsylvania, the Berkshires, White and Green mountains, and rivers of New England, the gorgeous blue lakes of Maine, were all that could be asked for in the way of superb landscapes. Most of us on the tour were normal persons, with sane ideas and opinions, but those mountains near Rangeley and in Vermont made us come very near raving over their beauty.

At Rangeley, by the way, we found considerable fun in a very serious melodramatic piece at the local opera house. It was entitled "The Convict's Daughter," and played on a stage that would have fitted into a hall room. We grew so enraged at the horrid villain that we nearly wrecked the show during the first act. His "dirty work" was more than we could stand. We livened up draggy parts of the play by interpolating dashy Glidden tour songs until some part of the second act, when we marched out, much to the relief of the natives, the company and the villain.

"THE MILLION DOLLAR KID."

RAPID TRUCK SERVING AS "BAGGAGE TRAIN"

Point Breeze Squabble Settled.

All is harmony now between the Quaker City Motor Club, the Norristown Automobile Club and the American Automobile Association, following an explanation by Secretary Edwin S. Nyce, of the Norristown club. The squabble arose when the Quaker City Motor Club learned that the racing board of the governing body had granted a sanction to the Norristown club for a meet that was to have been held at the Point Breeze track, Philadelphia, last Saturday, 25th inst. The Philadelphia club considered the invasion of the Norristown club rather presumptious and complained to the American Automobile Association, whereupon the sanction was rescinded. Secretary Nyce explains the Norristown club's position in the matter by saying that for a slight service rendered to his club by I. C. Minford, a Norristown promoter, some time ago, he agreed to procure a sanction for Minford's proposed meet at Point Breeze. According to Minford the enterprise was purely a private one for which only he and a friend were responsible. He says that all the moneys received from the sale of tickets, as well as all the entrance fees have been returned, and the only losers are himself and his associate, who had purchased a number of trophies and incurred considerable other expense incidental to the meet. As the American Automobile Association has since appointed a special committee to examine into applications for sanctions, it is thought that future mixups of the sort may be avoided.

Good Tire Record on Glidden Tour.

Reports compiled by observers and given out by the Diamond Rubber Co. show an average tire cost per car of $46.91 for all cars in the Glidden tour, contestants and non-contestants. The average cost for Diamond tires alone was $16.88, considerably better than the average for the whole tour. The average cost per car for tires excluding Diamond equipment, according to the same authority, was $64.94. The basis of cost is taken with size 34x4 representing the general average of tire sizes used. All items, even punctures, etc., capable of ready repair, are taken into the account, but the big feature of the tire cost was the blowing out of casings and tubes. Of 61 blown-out tires all told, the number of Diamond tires so damaged was five, with 21 contesting and non-contesting cars using the Diamond make. Of the 22 contesting cars with perfect scores at the end of the tour, nine were equipped with Diamond tires. Two cars changed to Diamond equipment en route.

DECLARES CITY LAW PARAMOUNT

Illinois Court Holds that Local Automobile Regulations Supersede State Law—Hits at Class Legislation.

Automobilists of Illinois are interested in the decision handed down last week by Circuit Judge Craig, who holds that local ordinances take precedence over State laws. The decision was rendered in the case of A. G. Woodbury against Dr. J. Addison Brown, of Champaign.

In arguing on a demurrer, counsel for the defense held that automobiles were entitled to go at a speed of 15 miles an hour, as that is the limit placed upon them by a law recently enacted by the Illinois general assembly.

The court held that the ordinances of the city of Danville which regulates the speed of vehicles on the streets should govern in all cases; that the legislature has no right to legislate for cities in that regard, and that the State law referred to should be disregarded.

It was held that in picking out automobiles from a score or more forms of vehicles and attempt to regulate their speed was a form of class legislation.

Jersey Justice for Joy Riding Chauffeur.

Having twice failed to appear before the Commissioner of Motor Vehicles of New Jersey after he had properly been summoned, Fred C. Tysen has lost his chauffeur's license, which has been revoked by Commissioner Smith. The reason for the revocation of the license lies in the alleged act of Tysen who, it is said, on May 25th last took his employer's automobile without permission, and, accompanied by some friends made a tour of Bergen county. During the trip the automobile collided with two peddlers' wagons; the accidents were investigated by the motor vehicle inspector of the district who forwarded a report of the matter to Commissioner Smith. Tysen was given two opportunities to present his defense, but when he failed to appear his license was revoked. He now will be subject to arrest if he attempts to drive a motor vehicle in New Jersey.

Pennsylvanians Plan a New Highway.

An improved highway across the State of Pennsylvania, from north to south and following the general course of the Susquehanna River, is the aim of a movement into which the automobilists of Wilkes-Barre have entered with spirit. It is the result of a proposal emanating from J. W. Hunter, State Highway commissioner of Pennsylvania, who suggests that the 67 counties of the Keystone State be connected by State roads. The Wilkes-Barre enthusiasts want a stretch of improved highway from Binghamton, N. Y., to Baltimore and declare this is by no means so much of an undertaking as may seem at first thought, as many stretches between the two cities already are in first class condition. They propose that the road shall go through Montrose, Tunkhannock—with a spur to Scranton—Wilkes-Barre, Bloomsburg, Danville, Northumberland, Duncannon, Harrisburg and York, meeting the proposed east and west Pennsylvania State trunk road at York.

Political Defeat Charged to Motor Car.

Charging his defeat to the unreliable running of the motor cars which were employed in connection with his election campaign, M. Jean Camper, who contested the Aisne Department against M. Doumer at the last general election for the Chamber of Deputies, sought and obtained damages from the company from whom the cars were hired. The bill for car rental for the eight days service was 600 francs, or about $120. In addition to this the outlay for repairs was included in the penalty imposed by the courts, and the sum of 200 francs, or $40, as balm to his personal feelings.

Novel Claim for Nullification of Sale.

Basing his action on the very novel claim that the engine is too powerful for the car, in consequence of which the frame failed to retain its shape, a citizen of Omaha, Neb., has brought suit against the maker of his car for $3,515, the amount paid for it last March. He claims that the car was sold to him on the representation that it was as good as certain other specified standard makes. Questioning the accuracy of the assertion he now wants to return the car, and seeks to compel the manufacturer to accept it and refund the purchase price.

Automobile Mail Service for Tinley Park.

Again have automobiles received official recognition from the United States government. This latest instance of progressiveness is apparent in the new arrangement made by the post office department for the use of motor cars to carry the mail from the Tinley Park post office in Illinois. Under the new order the three carriers of the rural mail have been supplied with cars and now cover their respective routes in a much shorter time than they did when horse-drawn vehicles were employed for the purpose.

Speed Limit Suspended for Taft.

"Casey, the Cop," whose swift motorcycle has enabled him to catch many speeding automobilists in New York, personally superintended a suspension of Manhattan's speed regulations, recently, in order that candidate Taft could cross the city quickly on his way to the President's home at Oyster Bay. The car, a White steamer, went across town in a whirl, and after crossing the East River ferry, gave Taft the speed he so much enjoys.

WOES OF THE FAMILY CHAUFFEUR

His Many Duties and Long Day of Labor—May Possibly Get Needed Sleep in the Winter.

When a chauffeur works for a whole family instead of for one person, he is not infrequently the victim of very long hours. The women of the household find uses for the car almost immediately after breakfast, for shopping, marketing, visiting the dressmaker, and other morning errands, while after lunch the car is kept equally busy in the round of afternoon social and pleasure trips. Sandwiched in between the periods when the women of the family are using the machine, come the calls to take the head of the household to and from his place of business or the club. In the evening the demands of conveyance to the theater, dances, concerts or receptions keep the chauffeur on duty until almost midnight, after which he is still subject to the call of his employer for nocturnal excursions that may last until 4 or 5 o'clock in the morning.

In some cases the chauffeur finds that the sequence of calls on his driving from after breakfast until dawn the next morning is not mere occasional happening, but a more or less regular thing. It is but natural that in such situations he should do a little grumbling to outsiders occasionally, relating his troubles.

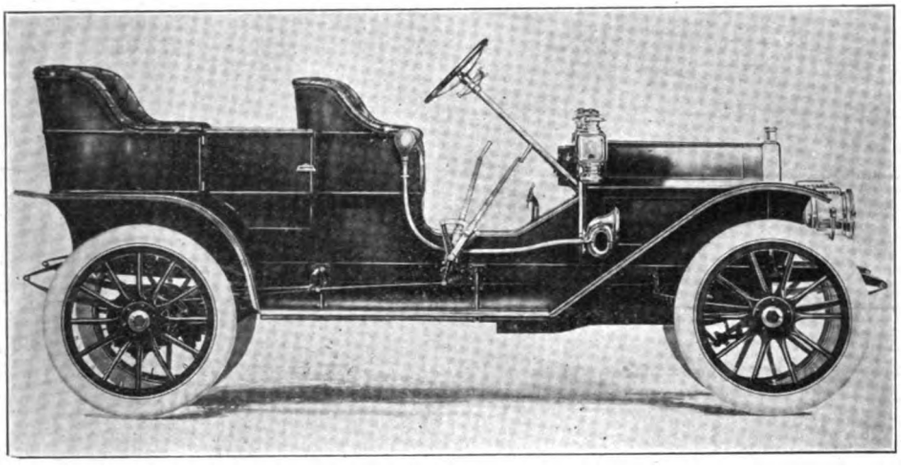
"When does your chauffeur get a chance to sleep?" asked the friend of a man whose car is in commission about 20 hours out of the 24.

"Sleep?—sleep?" repeated the chauffeur's employer. "Why he gets all winter to sleep, don't he." And he turned to other matters in a way to indicate that there was nothing more to be said.

Running Expenses of Ramblers.

In the Maintenance Number" of the Rambler Magazine are given statistics of the running expenses of about 200 Rambler owners, nearly all of whom are now driving their second, third, fourth or fifth Ramblers. The figures, which represent running expenses in 43 different States in the Union, are averaged to show a distance per car of 12,254 miles. Interspersed through the pages are letters from various owners stating their experiences in the matter of costs and giving numerous experiences which are of uniform interest. These include sundry rather novel commercial applications, sometimes of cars intended primarily for pleasure purposes.

Good Roads Lesson for Farmers.



In Colbert county, Alabama, at a recent assemblage of farmers, $12,000 was raised by the tillers of the soil with which to build an "object lesson" road, turning the whole matter over to a government expert.

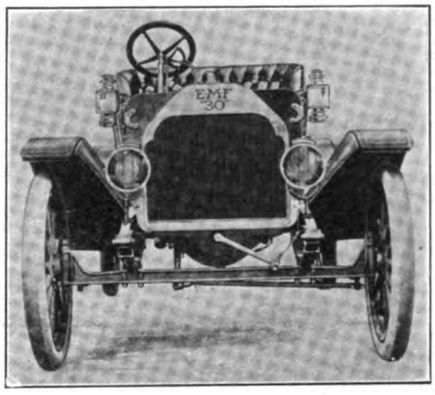
INNOVATIONS IN E-M-F MODEL

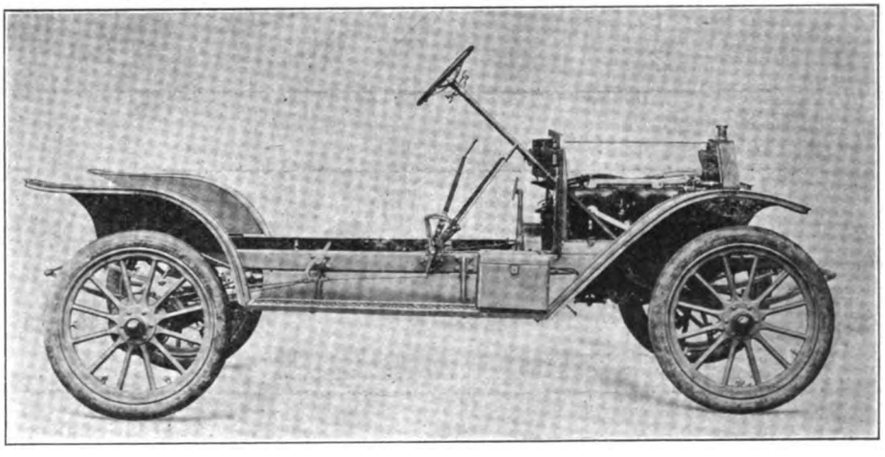
Characteristics of the Latest New Comer in the Automobile World—Details of Construction and Equipment.

Wholly aside from the interest stimulated by the announcements of the formation of the Everitt-Metzger-Flanders Co., Detroit's huge new concern, the E-M-F "30, details of which have just been disclosed, proves to be a marvelously complete study in design, and a most promising innovation to the five-passenger class of car. That such a car can be produced at the modest figure of $1,200, speaks volumes for the capability of the modern production engineer, as it does for the faith of the men who are his sponsers. In brief, it is a car built from designs that fail to reveal the marks of economy which its low selling price would seem to indicate, but which so far as they exist are not of a character to obtrude themselves upon the attention.

THE NEW E-M-F THIRTY—SIDE VIEW



BACK OF E-M-F THIRTY

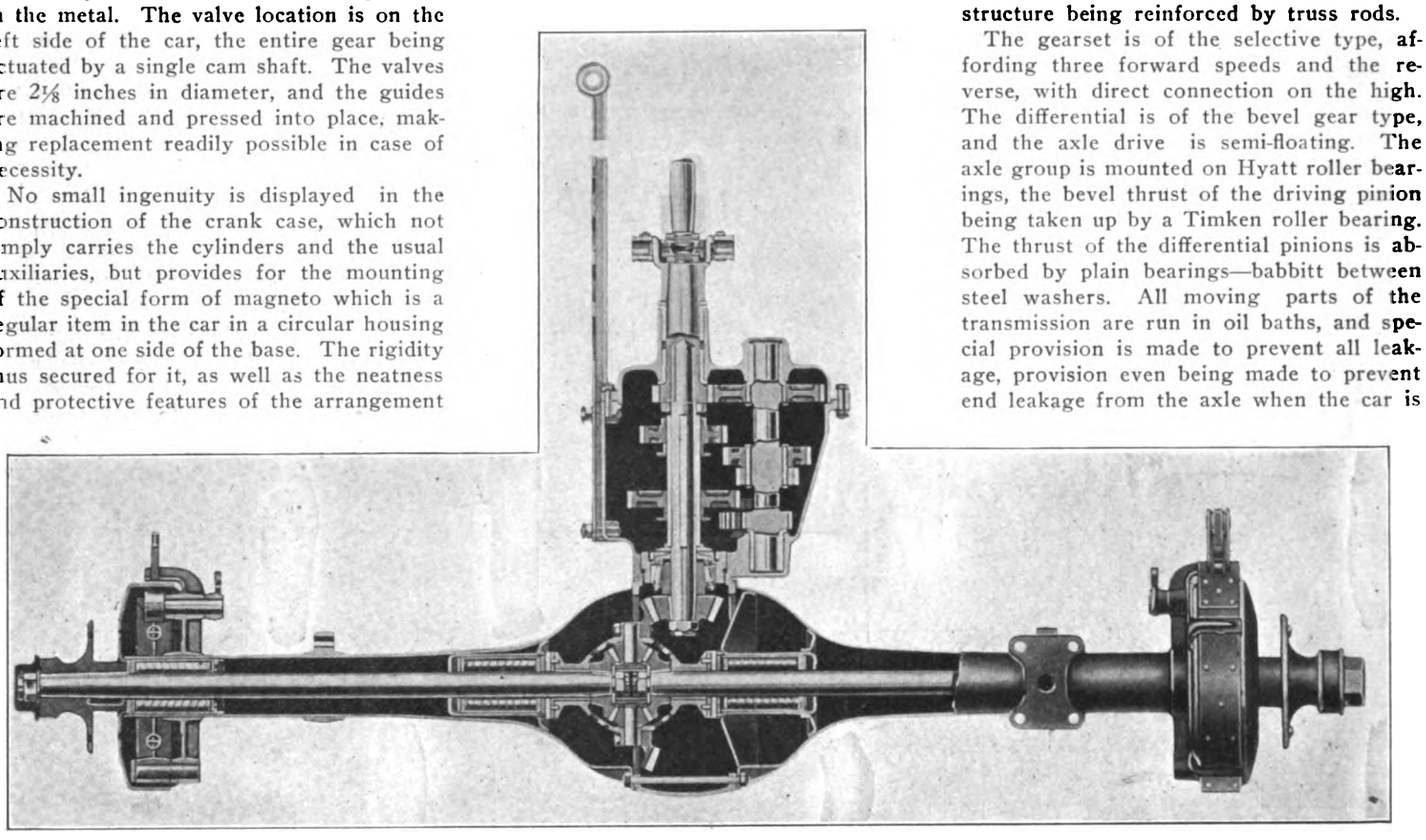


The general appearance of the machine, as may be gathered from the illustrations, is neat and sufficiently conventional, without being in the least suggestive of the unusual element concealed in its makeup. The touring body here shown, is but one of four types which are to be produced. The others are respectively, a runabout of standard form, a roadster, with single or double rumble, according to the taste and requirements of the purchaser, and a "demi-tonneau," which is heralded as "an E-M-F innovation,"—one of several, it should be mentioned in passing—which is a 4-passenger car of original form, having a detachable tonneau, which when removed, leaves room for trunks or other luggage or touring impedimenta. The raking steering column, long, sweeping fenders, enclosing the sides, seating arrangements and general mounting of the externals, are such as current usage has approved. The standard equipment, it should be added, includes side oil lamp, lamp, tube, horn, tire kit and tools, and the magneto.

The wheel base is 106 inches, tread standard, the weight of the touring car complete, 1,800 pounds. The wheels are 32 inches diameter, shod with 3½-inch tires all around. The brakes act on the rear hubs, are of the external-internal type, and are designed in such a way that the motion of the car after they have been applied tends to increase their pressure. The service brakes, being on the outside, are readily adjustable. The suspension comprises semi-elliptical front springs, and full elliptic, rear. All driving thrusts, traction and braking strains are taken by radius rods. The frame, which is of pressed steel is unusual in that it is of U section rather than the more familiar I-beam or channel type, and that it has perfectly straight side members, no offsets or bends being employed.

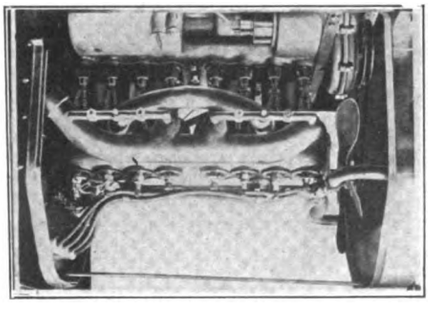
The mechanism of control is of the usual type, barring one important detail. That is to say, the motor control levers, instead of being placed on the top of the steering wheel, are located beneath it, and on the left side. The arrangement is such that they can be actuated by the fingers of the left hand without removing them from the wheel. The right hand thus is left free at all times for the manipulation of the brake and gear shifting levers.

FRONT VIEW, E-M-F THIRTY



CHASSIS OF NEW E-M-F THIRTY

Coming to the details of the power plant, the chief points of interesting design are brought out. As its designation indicates, the motor is rated at 30 horsepower—the use of unusually large valves, unobstructed and direct ports, and accurately balanced parts, being held to account for a nominal output somewhat greater than usually is assigned to a motor of 4 by 4½-inch cylinder dimensions. The cylinders are cast in



Digitized by Google

pairs, with integral jackets, the water space being carried entirely around the bores, thus providing for absolutely uniform cylinder temperature, and a uniform expansion in the metal. The valve location is on the left side of the car, the entire gear being actuated by a single cam shaft. The valves are 2⅛ inches in diameter, and the guides are machined and pressed into place, making replacement readily possible in case of necessity.

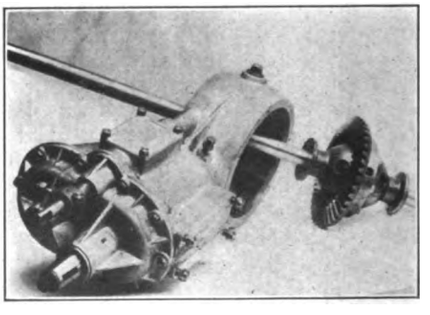
No small ingenuity is displayed in the construction of the crank case, which not simply carries the cylinders and the usual auxiliaries, but provides for the mounting of the special form of magneto which is a regular item in the car in a circular housing formed at one side of the base. The rigidity thus secured for it, as well as the neatness and protective features of the arrangement are particularly commendable. Contrary to usual practice, the supporting arms are not formed integrally with the case, but are of pressed steel, U-section, like the main frame, and at once stronger and lighter than the ordinary method of support.

REAR AXLE OF E-M-F THIRTY, SHOWING TRANSMISSION

E-M-F MOTOR

The crank shaft is offset ¾ inch, and in order to further improve the running of the motor, all reciprocating parts are weighed and balanced in the assembling process. The connecting rods are drop forged, the crank pin bearings being of equal length on each side of the rod. The bearings are lined with die-cast babbitt. The crank shaft bearings are a special babbitt, known to the trade as "white metal" alloy.

Lubrication follows the well-tried splash bath style, but is regulated by a constant-level system of control, with vacuum feed. This system is such as to permit the use of very large feed pipes—⅜-inch—without danger of flooding or loss of feeding control.



The ignition system includes in addition to the magneto, the dashboard coil, which is so mounted as to leave no wiring exposed; batteries distributor, and switch. It is important to observe that no portion of the system is exposed, all running parts of the magneto, like its drive, being fully enclosed in the above-mentioned crank case housing.

The cooling system follows the thermo-syphon plan, a belt-driven, stamped steel fan being the only moving unit included in it. The carburetter is of an improved float feed type, regulable from the driver's seat, and located on the right side of the car, away from all piping and other encumbrance.

The transmission comprises an unusually neat embodiment of the unit change-gear-axle type. The master clutch, which is an expanding ring, leather faced, is mounted in the fly wheel in the usual manner. The driving shaft is equipped with two universal joints, torsional resistances being taken up by a single torque bar, brought well forward on the frame.

The axle unit is composed of a right and left section, drawn from sheet steel and heat treated. It is of very light design, and embodies in its construction the much-discussed autogenous welding process, which ensures a practically perfect union of the parts. The center section forms the rear end of the gear casing, and is a casting, to which the end sections are bolted, the whole structure being reinforced by truss rods.

The gearset is of the selective type, affording three forward speeds and the reverse, with direct connection on the high. The differential is of the bevel gear type, and the axle drive is semi-floating. The axle group is mounted on Hyatt roller bearings, the bevel thrust of the driving pinion being taken up by a Timken roller bearing. The thrust of the differential pinions is absorbed by plain bearings—babbitt between steel washers. All moving parts of the transmission are run in oil baths, and special provision is made to prevent all leakage, provision even being made to prevent end leakage from the axle when the car is left standing on an incline or in running on grades. This attention to minor detail is characteristic of the construction throughout, and the design of the various parts discloses forms which in their adaptability to the most advanced manufacturing methods,

PARTIALLY ASSEMBLED TRANSMISSION

without a shade of sacrifice in efficiency so far as the finished product is concerned, show a most ingenious combination of manufacturing and designing considerations.

Supplementary spiral springs have created for themselves such a steady demand, according to the Supplementary Spiral Spring Co., of St. Louis, that the business this year is over 300 per cent. greater than it was last year.

ABOUT TWO-CYCLE ENGINE DESIGN

Requirements as Specified by E. W. Roberts in Address to Engineers—His Methods Stated and Explained.

While the fund of general information concerning matters relating to the design of the four-cycle motor is of fairly comprehensive scope, it is equally true that comparatively little is known outside the draughting rooms of the few successful designers, of the requirements of the two-cycle motor. On this account the information collated in the shape of a series of notes on two-cycle engine design, presented recently before the Mechanical Branch of the Association of Licensed Automobile Manufacturers, at a meeting held in Cleveland, is of no small importance as a matter of reference and record. The author of the address, Mr. E. W. Roberts, has held an enviable position as a gas engine authority for a number of years.

The relative power of the two and four-cycle types has been held in question for a long time. Mr. Roberts states it as his experience, that about 1½ times as much power can be obtained from a two-cycle as from the more common type. A new two-cycle motor of 4½ by 5 inches cylinder dimensions, has been found to develop 19.89 brake horsepower.

One characteristic of the type, which he mentions as important in connection with its service in automobile work, is the fact that in general it develops more power in proportion at low speeds, and holds up its load tenaciously when doing heavy duty. "This is due," he explains, "to the fact that they are low in torque at high speeds, owing to being choked. . . . . The speed of the air entering the crank case during 90 degrees of the piston travel and at 900 to 1,000 r. p. m. . . . . is enormous. As I remember, a 4½-inch by 5-inch intake figures out 190 feet per second at 900 r. p. m. With a 1½-inch intake, the port will be about 2¼ inches long, measuring along a chord of the cylinder bore. With a 2-inch intake, the area is ⅝ inch greater and the ports are correspondingly longer."

Turning to the very important feature of timing and the laying out of the cylinder ports, he says:

"The usual practice, as I have seen it, is to open the inlet valve at or near the head center and hold it open until the other center is passed. . . . . The practice I have always gone on in the opening of the intake, both in the four and the two-cycle, is to hold open as long as possible without blowing back at moderately low speed. In two-cycles, the time of opening is limited in this way. If we are to use only one carburetter on a four-cylinder engine, we must not have two intakes open at the same time, and, therefore, we have to use a little less than 45 degrees on each side of the center. So the intake must be open a little less than 90 degrees; 43 to 44 is about what I use.

"The exhaust timing is not so important in this regard, if the exhaust is so carried off that the gases from the various cylinders will not interfere with each other.

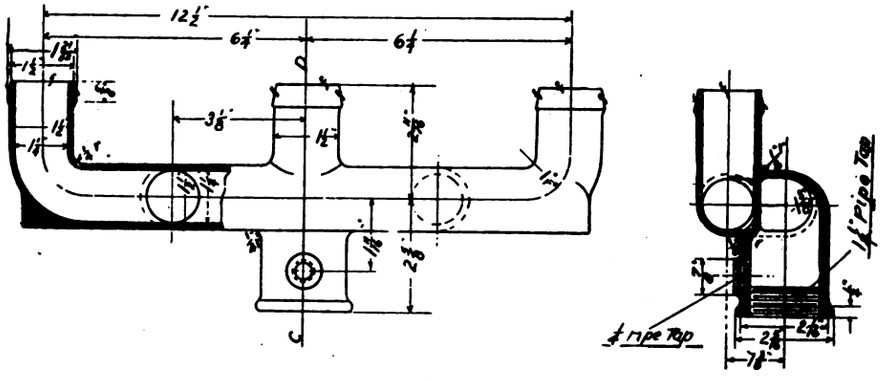

Fig. 1

"For the intake port to the crank case, I usually leave an opening as follows: I would start to open the port 44 degrees before the piston reaches the head center. You know that this port is opened and closed by the lower edge of the piston. The opening and closing will take place at the same angular position of the crank pin. This will, you see, leave the intake port open during 88 degrees of the crank circle. Now in a single, or two, or a three-cylinder engine it is practical to leave the port open a little longer, and I have used as much as 48 degrees on each side of the center, without a blow-back through the carburetter.

" . . . . The cylinder inlet port or that which communicates with the transfer port leading to the crank case (in the plain, three-port engine) . . . . can be kept open for the same time as the inlet port to the crank case, i. e., about 90 degrees. In the large ported, high speed motors, I have had to reduce this somewhat. It must be remembered that the cylinder intake port should open after the exhaust port. This is in order to allow the pressure in the cylinder to fall below that in the crank-case before the port leading to the crank case starts to open.

"It is my custom to make the opening of the exhaust about 58 and 59 degrees on either side of the center. It must be remembered that the exhaust must not only open soon enough but it must also open full enough to prevent any chance of the hot gases rushing back through the transfer port to the crank case, and thus cause a crank case explosion, or, as it is often called, a 'backfire.'

"You can prevent this to a certain extent by the use of a screen in the bypass, but I have very little use for a screen as a rule because they are troublesome to take care of. They choke up very easily and the easiest way to clean them is to put in a new one.

"As I have already pointed out, in the ordinary type of slow speed marine engines with small port areas I have used 90 degrees as the port opening for the cylinder inlet. But when I enlarged the ports for efficient running at high speed, this angle proved too great. I am unable to tell you the exact angle off-hand, but on 5-inch stroke the distance along the piston travel was reduced ⅛ inch.

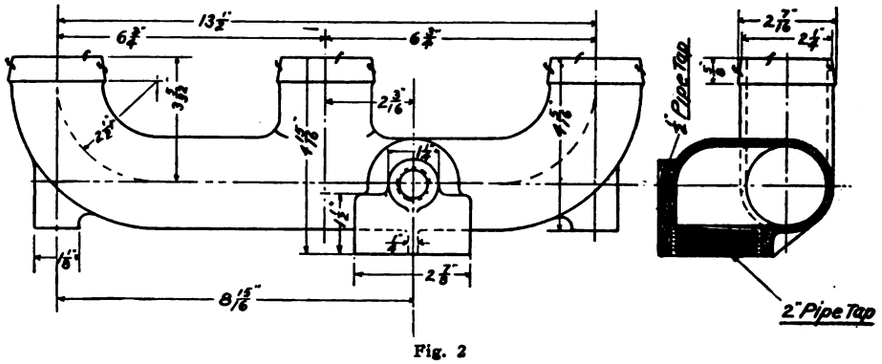

Fig. 2

" . . . . When laying out the ports of a two-cycle, ... always lay out the angles on the crank circle and work to the points these angles will give you, and remember that it is a case of time and not distance. Another thing you must bear in mind. That is, the shortness of the time that the two-cycle three-port intake is open as compared to a four-cycle. You must have a larger area than you would with a longer opening. While the crank case inlet

Digitized by Google

of a two-cycle motor is open by 90 degrees, the inlet valve of a four-cycle is open anywhere from 200 to 210 degrees. Let us say 200. You will see, therefore, that you have in a four-cycle more than twice the time of opening that is employed in a two cycle of the three-port type. Hence the area of the intake must be more than twice as great in the latter as in the former. Common practice is to keep the average speed of the ingoing air at the normal speed of the engine, down to 100 feet per second.

"In order to keep close to this speed in a 4½ inch by 5 inch engine, I have had to use a 2 inch carburetter. That would be enormous on a four-cycle, as about 1¼ inch would be ample.

In order to keep the rings from jumping in the ports when they are so long it is necessary to use bars across them. I find the best way to make an exhaust port bar is to core it hollow and run water through it. . . . .

"The lowest crank case compression that I have found to give good results is 4½ pounds. I usually aim to get between 6 and 8, and most of my engines have 8 pounds. . . . . .

"In my judgment 8 pounds is about right, and I find if I go beyond 10 pounds I am likely to get into trouble. You will find that a great many designers who are just starting on the two-cycle engine proposition have the impression that it is necessary to get the highest possible pressure in the crank case. And, in order to get it, they use filling blocks, that is, discs attached to the crank webs. I find that by making the crank case as close to the moving parts as possible, leaving approximately ¼ inch clearance, I usually obtain 8 pounds crank case compression. In other words, I follow as closely as possible the path of the crank shaft and the connecting rod.

"With reference to keeping the crank case tight, there is a mistaken impression that as the engine wears the crank case will leak along the shaft; and quite a number have attempted to use packing to prevent it. This can be done quite readily on single cylinder engines, but on a multiple-cylinder it becomes quite a difficult proposition. The best practice is to use something that will stand the wear and use a comparatively long bearing; I am using die-cast nickel babbitt. . . . .

"Crank case explosions are due generally to the exhaust gas in an incandescent state rushing down through the transfer port and setting fire to the mixture in the crank case. Sometimes they are due to an overheated crank case. . . . . the period of inflammation of the mixture is the same in fractions of a second for the same proportion and for weak mixture the period of inflammation is longer than for high compression and rich mixture. Now one of the necessary points in avoiding crank case explosions is to get the flame out when the intake port opens so as not to set fire to the incoming charge, that is, the charge that is entering the cylinder from the crank case. Therefore, when running on low compression, it is necessary either to enrich the mixture or advance the spark. Therefore you can quite often stop crank case explosions at low speeds, or in fact at any time, by advancing the spark. . . . .

There is quite a little importance in designing the deflecting plate so as to get the best results. I get very good results by turning the ends of the deflecting plate toward the cylinder wall. In large engines the top of the piston should slope away from the deflecting plate towards the exhaust port. The deflecting plate should project from the piston as far as the clearance will allow, making it reach within about 3-16 inch of the cylinder head when at the end of the stroke. . . . .

"The best position for the spark plug is, I believe, directly in the center of the cylinder. If it is placed on the side of the cylinder, especially on the exhaust side, it is apt to require too much lead. The two-cycle engine is very sensitive to spark plug placed in a pocket; for it will increase the lead and if you do not get enough lead at light loads you are very likely to get crank explosions. . . . .

"For the exhaust manifold I use a long curve in the form of a U which leads the gas from two-cylinders. In a four-cylinder engine I join these two by a long curved Y pipe so designed that the exhaust does not interfere with that of another pair of cylinders. With three cylinders or less we do not have to be quite so particular, but still it is best to let the exhaust out with as little resistance as possible. In my small motors I use a straight pipe with the branches from the various cylinders curving into it. This makes a very convenient form, but is not quite so efficient as the manifold with the large curves.

"The intake manifold needs careful attention, and if not properly designed will cause one cylinder to get more gasolene than another so that while one cylinder is getting the proper mixture the other will be flooding. The best form of intake manifold for a three-cylinder engine is shown in the accompanying drawing (Fig. 1). In another form I tried bringing the mixture down from above so as to raise the carburetter and found that the reversing of the current has a separating action and causes the gasolene to deposit in the corners of the manifold. It was compelled to abandon the pouch and go directly to the straight pipe joining the three cylinders, as shown in the illustration of the larger manifold (Fig. 2). . . . .

"No matter how well designed your intake is, if the carburetter does not give a homogeneous mixture, one cylinder is sure to get more gasolene than the others. The carburetter must be such that it will give a homogeneous mixture. You must remember that the suction from the intake port of a three port engine starts with a high vacuum and the air goes through the carburetter with a rush. For example, when one of our large engines is running by a belt at 300 revolutions, a board held ¾ of an inch from the opening will be pulled out of your hand. In fact, I have placed a box weighing 8 pounds against the intake and the suction held it there. . . . .

"I formerly held to the opinion that the only proper place for a throttle for a two-cycle engine was in the by-pass or transfer port. The theory was that if you throttle at the carburetter you weaken the pressure in the base, and that the pressure in the base being lowered would not resist the rush of the flame from the spent charge in the cylinder. I assumed that by throttling in the by-pass I would retain the pressure in the crank case and at the same time choke the passage and between the two prevent the burning mixture from rushing down into the crank case. This proved good practice with an ordinary carburetter that did not give a good mixture, but by using a carburetter which gave a good mixture I found I got better results by throttling at the carburetter. . . . .

The only thing that I take into consideration (in connecting rod design) is the clearance in the crank case and try to make it as close as I can; and I always use as short a connecting rod as possible; 1.8 times a stroke is about as short a rod as I dare use. For instance, I would use a 9-inch rod for a 5-inch stroke. . . . . If you wish to hold the same conditions in one engine as in another, you must keep the area in the same proportion to the stroke. From 3½ to 4½ times a stroke is the area that you will find gives the best results. I have designs in all kinds of proportions. The bulk of them I have made run from 4½ by 5, to 3 by 2½. . . . .

"The construction of two-cycle engines requires very careful work. I find it advisable to mill the ports by using a milling cutter of small diameter and drop the cut right into the port. This gives the right width and the right distance from the end of the cylinder. If you do not get your ports right you will get into trouble. A great many manufacturers file them to gauges, but this is troublesome and inaccurate. You really have got to grind a two-cycle cylinder to get good service, because a reamer will jump more or less in going over the ports."

Extinguishing a Carburetter Fire.

A simple method of extinguishing a carburetter fire, given by a foreign expert, is that of turning off the main fuel supply from the tank and racing the engine. This, it is claimed, will tend to create sufficient draught through the intake pipe to keep the flames within reasonable limits, while the amount of fuel contained in the float chamber is so small that the fire will soon waste itself without doing any damage, expiring as a matter of course as soon as the fuel is exhausted.

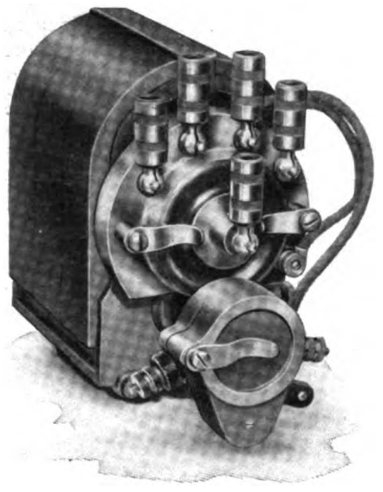
MAGNETO WITH STATIONARY COIL



How the Armature is Supplanted in New Remy Device—Arrangement for Provisional Use of Batteries.

One possible objection to the construction of the ordinary type of magneto is that in the production of the primary current, the inert battery is replaced with a moving part—the armature—in which the current is generated, and from which it must be conducted to the transforming and distributing devices through a moving contact. Except for this, the apparatus employed is practically the same as that required for the more familiar battery and coil system. In the Type "L" Remy alternating current, high tension magneto, which has just been brought out by the Remy Electrical Co., Anderson, Ind., this objection is eliminated by the use of a stationary coil. The "inductor," corresponding to the armature of the ordinary magneto consists merely of a simple forging mounted on a steel shaft. The simplicity thus secured constitutes an asset of no mean value.

In its general construction, the magneto is of conventional pattern. Let into the pole pieces of the magnet is a single coil of No. 18 magnet wire. The "lines of force" of the magnetic circuit, passing through this, are reversed at each half revolution of the driving shaft, thus generating two current waves in the wire for each revolution. The primary winding thus constituted is connected with the primary of a non-vibrator spark coil, an interrupter, properly adapted to the type of motor to be ignited, being interposed in the circuit. By special design, the "current wave" is of considerable duration, thus permitting considerable latitude in timing, and the circuit is mechanically broken, during the period of its maximum intensity. Variation in the time of the break is accomplished by shifting the circuit breaker around the shaft on which the cam is mounted.

After passing through the coil and being "stapped up" to the high tension suitable for ignition purposes, the current is returned to the distributor of the magneto, through a single wire. The arrangement of the latter as well as the speed of the driving shaft, depends upon the number of cylinders to be fired. With the four-cylinder, four-cycle motor, the inductor is rotated at the speed of the crank shaft. With the six-cylinder, four-cycle motor, it is driven at one and one-half times the speed of the crank shaft. With the double-opposed motor, the inductor is driven at the same rate as the crank shaft, but the distributor is omitted, and the circuit breaker is fitted with a single cam.

Provision is made in the construction of the coil and switch, for the use of batteries in connection with the magneto, but without the use of a second coil. The switch also is provided with a push-button for use in starting "on the spark," when the batteries are in circuit. As the coil is intended primarily for magneto service, it is capable of handling an unusually high current strength, so that a very strong starting spark is produced at the plugs. While the batteries are in service, the current passes through the magneto, the regular distributor taking care of the secondary circuits. In this way, the system acts in precisely the same way as when being used with the

self-induced current, except that the primary is derived from a constant source.

Successful Handling of Tires.

It is a fact well known to tire men as well as to motorists of experience that tire life depends to a very great extent upon the skill and faithfulness of the driver. The rules for success in handling tires may be summarized as follows: First, find the maker's rule for inflating tires of the size and type employed on the car; then use a suitable gauge, and test them with sufficient frequency to maintain the correct pressure practically all of the time. Drive as straight as possible, avoiding car tracks and ruts as far as may be done, taking care not to turn the steering wheel any more abruptly than is absolutely required by the emergency. See that the differential gearing works freely and that neither of the brakes drags sufficiently to interfere with its action. Keep the tread surfaces free from oil, pick out loose gravel which may become embedded in the surface from time to time, close all small cuts promptly, and above all, learn to remove and replace the tires without pinching the tubes or tearing the beads on the shoe.

One of the Small but Important Parts.

One of the smallest pieces, and yet as important a part as any on an automobile is the minute platinum contact piece on the end of the adjusting screw of the coil and on the blade. Though an essential part it seldom exceeds one-sixteenth of an inch in any dimension.

TESTING TORTIONAL STRESSES

Experiments Show Ratio of Actual Strength of Propeller Shaft to Possible Strain—Big Factor of Safety.

Of interest as showing how far the factor of "guesswork" has been eliminated from the processes of designing and constructing automobiles, the results of a special test applied to the propeller shaft of the Rambler car may be taken as a typical instance. Under ordinary circumstances, the chief stresses brought to bear upon the shaft are torsional, or twisting, and due to the driving effort of the motor, on the one hand, opposed by the tractional resistances at the wheels, and the frictional losses in the transmission, on the other. Therefore the test applied to prove the actual strength of the shaft in relation to the work it may be supposed to be likely to perform, was a torsional test.

For this purpose, a short measured length of one of the regular shafts, together with the squared end upon which the gears are mounted, was gripped in the torsion machine and twisted, by means of a rack and pinion having a 2¼-inch radius of action, which corresponds exactly to the length of engine crank. The opposite end of the shaft being held perfectly rigid, the entire load was absorbed by the fibers of the shaft.

In this way it was found that 12,000 pounds pressure was necessary in order to twist the shaft, while a permanent "set," or distorsion, was developed under a load of 13,000 pounds. Under 14,000 pounds pressure, the squared portion of the shaft yielded, but was not permanently distorted until another thousand pounds had been added to the load, when the test piece was removed from the machine. It was then found that the shaft had been permanently twisted through a half turn, but without developing any sign of rupture. When it is stated that the maximum calculated pressure derivable at any moment from the engine is 2,800 pounds, the actual leeway allowed for emergency strains, or in other words, the factor of safety, is apparent.

Wheel to Ease the Work of Steering.

Efforts to improve the design of steering wheels, to make them as restful and convenient to the hands as possible, have not abated. One of the latest of the new ideas developed is a steering wheel form in which the rear half of the wheel rim has been cut away and a spade-handle form of grip mounted on each side. For all ordinary steering the effect is much like lever control, but when it is necessary to turn the steering mechanism to an extreme position, the rim on the forward part of the wheel is ready to the hand, so that it is not necessary to keep to the handles if they revolve to an awkward position.

BRAND NEW ALLOY OF ALUMINUM

"Magnalium" Said to be Stronger and Lighter Than Its Basic Component—Its Greater Adaptability.

Among metals developed in connection with motor car construction perhaps none has been more rapidly advanced from a state of comparatively insignificant use to one of extreme importance than aluminum. Notwithstanding the almost universal extent of its present application, however, its use is limited by several considerations—among them its strength, and the fact that it cannot be forged, welded, or even soldered by ordinary processes. In a new alloy, "Magnalium," which is produced by the Magnalium Syndicate, of Berlin, Germany, many of these defects have been removed, as is claimed, by the introduction of a low percentage of magnesium.

Its value, particularly as applicable to automobile construction, is shown by the statement that it can be forged by hand or drop hammer, handling about like Swedish steel, and that it requires no special skill in treatment, so that it can be worked by the ordinary blacksmith or foundryman. Furthermore, it can be soldered by the use of a special solder, although it cannot be welded. It can be produced in rolled plates, bars, rods, wire and tubing, and in any form shows greater strength than the ordinary aluminum alloys, despite the fact that it is lighter. In machining, it is said to work much like brass, taking about double the tool speed of aluminum. It resists oxidation successfully, is not affected by dry or damp air, water, ammonia gas, carbonic acid, and most organic acids. It is slightly affected by sulphuric acid, and more rapidly by alkaline solutions, while its sensitiveness to the action of salt water is not sufficiently marked to be objectionable.

The specific properties of the metal, which is produced in several grades, ranging in composition from 90 to 98 per cent. aluminum, are given by its makers as follows. Specific gravity, 2.5, as compared with that of ordinary aluminum, which is 2.64; electrical conductivity, 56 per cent. that of pure copper; melting point, 1,185 to 1,250 degrees F.; specific heat, 0.2185.

Its strength, varying with the method of treatment, is given by the following comparisons. Sand castings, of "Class X" magnalium, 18,491 to 21,336 pounds per square inch, with a reduction of area of 3.75 per cent.; chilled castings, 22,759 to 25,604, with a reduction of 3 to 8 per cent.; Class "A," (90 per cent. aluminum), 69,890, with a reduction of 4.19. The strength increases under rolling and drawing treatment, the hard rolled plates of Class "Z" showing 52,203 pounds per square inch strength, with a 3.7 per cent. reduction, drawn wire, 41,000 to 53,000 pounds; drawn rods, 60,000 pounds, and drawn tubing, 74,000 pounds per square inch.

Magnalium is in use abroad in the manufacture of small utensils, such as ordinary aluminum has been employed upon more or less extensively, and in all branches of light manufacturing. Samples of the metal exhibit a close grain, characteristic white color, take and hold a good polish, and in the form of plates and rods, show a surprising amount of elasticity and strength. For instance, a spring wound from wire of about 3-16 inch section, for purposes of demonstration, develops a resistance which is really surprising. The American agency for the metal has been taken by Morris R. Machol, of New York City, who imports it in ingot, or in special forms as may be required.

To Clear a Cylinder of Fragments.

It occasionally happens that a broken valve or spark plug proves a source of considerable annoyance and expense because of the difficulty of removing the broken fragments from the cylinder. This difficulty is most likely to arise in motors which have cylinders mounting the valves in offset pockets, so that there is no really sizeable opening directly into the bore proper. Sometimes, probing with a wire or a pair of long-nosed pliers will suffice, but more often, the parts must be left in the cylinder to work whatever harm they may, while the car is run to the nearest garage on the other cylinders, pending opportunity to take down the cylinder and clean it out. A simple kink, suggested by one who has had plenty of experience of this sort, is that of jacking up one side of the machine as high as is possible, taking advantage of the pitch of the road at the gutter, whenever possible, and after removing the valves, cranking the motor as rapidly as possible. The loose particles of broken metal or porcelain will then be thrown upward by the piston, and ultimately will hop out into the valve pocket, from which they can be removed without further difficulty.

Speedometer Driven from Live Axle.

Although it has been supposed hitherto, that the constant action of the differential and the slippage of the driving wheels would prevent the successful exploitation of a speedometer made for attachment to the rear of a chassis, a British maker has had the courage to undertake the production of such a device, intended to be driven from the propeller shaft of live axle cars. Several points of advantage are claimed for the system, while it is asserted by the makers in question that the rear wheel slip, contrary to the general impression, is practically negligible.

Give the Battery Plenty Acid.

Users of storage batteries should bear in mind that the "life" of the battery is seriously affected if the acid does not cover the plates.

CARE OF THE IGNITION SYSTEM

Why the Insulated Wires Require Special Attention—Causes of Trouble and How to Combat Them.

Most of the ignition troubles which used to be such a bug-bear to the private owner, have now been removed by improvements in the design of the ignition system—a work of salvation for which it is impossible to give too great credit to the manufacturers of ignition apparatus. At the same time the present day owner who is at all neglectful, frequently finds himself in difficulties from which the only way out is the expensive and time-absorbing one of complete or partial re-equipment. That such dilemmas most commonly are caused by neglect, is aptly proved by the dearth of experiences of such a nature among users who are willing to devote a proper amount of time and attention to the work of maintenance of the machine.

"Probably there are no conditions so severe for insulated wire as those existing with the wires of the electrical ignition apparatus on a motor car," says a foreign expert whose experience in other lines has led to this conviction. "The constant vibration, dirt, dust, moisture, oil, that are constantly flying about all bring very severe strains upon the insulating envelope of the cables. Oil quickly softens rubber, and causes it to lost its insulating properties. Dirt and moisture have a nasty knack of getting at connections where wires enter, or pass under screws, and promptly commence to attack them. The vibration of the car is constantly tending to drive the metal parts through the insulating envelope of the conductors and to break wires off short at screws.

"All of these troubles can be guarded against and the ignition apparatus kept well up to its power, day in and day out, year in and year out, provided that it is well laid out in the first instance, and provided that some one is constantly on the lookout for possible causes of trouble. The cleanest of clean housemaids, if she could be set to keep the component parts of an electrical ignition apparatus clean, could not produce results too good for the requirements of a motor car."

Removing Gear Wheels from Shafts.

When attempting to remove sprockets or other gear wheels from shafts to which they are attached by means of taper or plain fits and keys, care should be taken not to use the hammer too freely, for fear of either fracturing the gear or springing it out of line. A so-called "pulley-puller," or special jack may be contrived without difficulty under almost any circumstances, and by its use the part may be removed without imposing any undue strains upon it.

UTOPIA FOR THE AUTOMOBILIST

Ladies in Palmer Plan to Create the "City Automobile"—Not a New Vehicle, but a New Metropolis.

It all came about at a recent meeting of the Old Center Improvement Club. What? You haven't heard of the Old Center Improvement Club? Then perhaps you've never been touring over the sandy roads of a certain part of Massachusetts, tired, dusty and thirsty, with acres and acres of sand and never a drop—of water—to drink, and then suddenly run kerplunk into the free rest room at Palmer that was established by ten estimable ladies of Palmer's "old Center," and one of those ten estimable ladies poured out a cooling glass of lemonade for Marjorie and gave you a glass of iced tea—at least it looked like that only it had a spring of spearmint propped between the chunk of ice and the maraschinoed cherries—and you settled down in that big leather arm chair over by the northeast window and just blessed one-tenth of those ten estimable ladies and wished you could settle down there for life.

No? Then you don't know what you've missed.

Well, anyway, it was those same estimable ladies that form the Old Center Improvement Club, who were sitting in the automobilists' rest room the other day sipping their eau de vie de Dantzigs which has the cute little fiddlededees trickling down that somehow just remind one of a rainbow suddenly falling to pieces and dropping through the sea, when President Etta King Ogle's countenance suddenly illuminated.

"Just the very thing! Perfectly grand for automobilists!"

"Prithee tell us, please," implored the other nine.

And then the presidentess unfolded the plan that will make Utopia for the poor, lonesome automobilist who, like Eugene Sue's "Wandering Jew," have had to peregrinate around the country with no homes of their own. Some of them may have paused in out of the way corners like New York, Philadelphia, Boston, Chicago, or Barnegat, but other plebeians lived here too, such as horse drivers, steeple jacks, artists, tug boat captains, brokers, and others. But aintitawfulmabel that there hasn't been a place just for automobilists?

It will not be so long, for that memorable meeting in old Palmer some time ago marked an epoch in the history of automobiling that will go down in the annals—but anyhow, here jumps the cat right out of the bag. Sssssh! Don't tell any one just yet, for it may not happen, but the estimable ten ladies who form the Old Center Improvement Club, which built the automobilists' free rest room 1½ miles from Palmer, intend to build the "City Automobile."

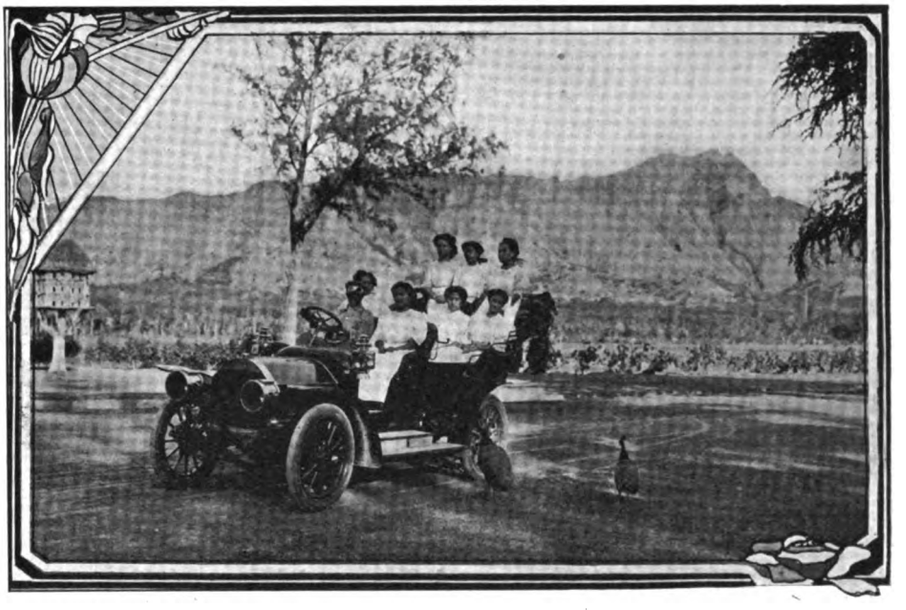
The "City Automobile" will be situate in—quoting from the presidentess—"the old historic Center, a bit of country more lovely than any on earth. Bold and picturesque scenery—noble hills shouldering the sky—rich meadows interlaced with trout brooks. Just the spot for a lovely City Automobile . . . . . better than Lenox."

Don't think this is an advertising scheme. Far be it from the estimable ladies of the Old Center Improvement Club to foist a "scheme" on an unsuspecting public.

Not at all—"the thought was born from reading of the country persecution of the autoist (quoting Presidentess Etta King Ogle again) and it became crystalized, to plant a city of wealth and homes right here in this beauty-field, skirted with forests, fine heights . . . . no noise, no dust from the railroad," and in fact, lots of other things one column three inches running over into the next line long.

If it hadn't been for the fact that the lawyers' and business men's clubs around old Palmer were slow the women wouldn't have taken things into their own hands but, being imbued with the true Western spirit, as they say—

And that's the answer.



Boston Gets Its Taxi-Motor Cabs.

Taximeter motor cab service was inaugurated in Boston, beginning last week, when twenty-five vehicles built for the service by the E. R. Thomas Motor Co., of Buffalo, N. Y., were put in commission by the Taxi-Motor Cab Co. There was immediately a demand for them by the citizens of Beanopolis, who are obliged for the present to call a cab by telephoning to the company's headquarters in the Motor Mart. Regular stands will be established within a few days. The rates of fare, as fixed by the Police Commissioner, are similar to those established in New York City.

ON HAWAII'S BEAUTIFUL ROADS

Where Grandchildren of Savages Ride in the Most Modern of Vehicles—Attractiveness of the Islands.

While the automobile has become a more or less familiar sight in almost every part of the world, in many countries and places it still is somewhat of a curiosity. In many climes the impression exists amongst the semi-barbaric and barbaric inhabitants that the self propelled motor car is some sort of a "devil wagon"—and the natives employ this description of the vehicle with a far different meaning than does the Anglo-Saxon. To Glidden, and others like him, many hundreds of people are indebted for their first and only sight of an automobile, and while to these strange and almost unknown races the motor car still is, and for many years will be, an object of intense wonderment, it gradually is finding its way into more general use throughout the civilized world and to-day is unnoticed in countries where a very few years ago it would have been a marvel.

BEVY OF HAWAIIAN BEAUTIES JOY RIDING NEAR HONOLULU

One of the very attractive places for automobiling is the Hawaiian Islands, as is shown by the accompanying illustration, which depicts a Studebaker car on the roads near Honolulu. The condition of the roadway, the picturesque scenery, together with the long days and cool evenings of tropical countries supply conditions for motoring which readily account for the popularity which motor cars have achieved in this portion of the tropics within a comparatively short time. The presence of the most modern of vehicles on well kept roads through regions where cannibals dwelt little more than a century ago is a striking illustration of the progress of civilization.

NEW RESTRICTIONS IN THE PARKS

Ordinance Adopted Bars Out Vehicles Emitting Smoke and Nauseous Vapors—Many Complaints Reported.

At a meeting of the New York City Park Commission, held Thursday last, 23d inst., a rule was adopted which aims to exclude from the use of the park highways of the city, automobiles that emit smoke and nauseous vapors. The ordinance reads: "No person shall be permitted to run a motor vehicle in the parks or parkways of this city, under the jurisdiction of the Department of Parks, which emits from the exhaust or muffler thereof offensive quantities of smoke or gas or disagreeable odors."

In discussing the new rule, Commissioner Smith said that he had received many complaints from drivers and others who use the parkways, to the effect that the smoke and odors from many machines made driving almost intolerable.

"The taxicab companies were most complained of as offenders," said the commissioner, "and I had the park police take the numbers of all machines that smoked. These I submitted to their owners, but the cars still smoked."

Incidentally, he mentioned the danger in driving behind automobiles from which heavy smoke or ill-smelling gases come, and remarked that a like measure had long been in force in other cities. The ordinance goes into effect on August 1, and Captain Farrell, in charge of the park police, was ordered to explain the new order to the park policemen and to instruct them what action to take.

Rock Island to Impose a Wheel Tax.

Chicago, in imposing a wheel tax upon all vehicles, and in securing a court decision in favor of the legality of that tax, has set an example that other Illinois cities might be expected to follow as a matter of course. Rock Island is the next to look with favor upon this new method of shaking down, the chief victims of which naturally would be automobile owners. The intended victims, however, are doing their best to prevent the city council from adopting the ordinance for the purpose which has been introduced. They have been trying to show the city fathers its unfairness.

Police Testimony Fails to Convict.

When the automobilist falls into the hands of the trap operating country cop, it is almost a cinch that the average cost per mile of his trip will be swollen by the addition of a fine, for the cop's word goes, as a rule. But there was a notable exception the other day when Charles N. Fitts, of Newton, Mass., was haled before Judge E. B. Pratt, in the district court of the town of Hingham and, without lawyer or witness, succeeded in convincing the court that the three policemen operating the trap could not have timed him correctly. After hearing the testimony of the policemen Mr. Fitts testified that he had a speedometer on his car and just as he entered Hingham he noticed the large sign that he never saw before asking the automobilists to keep the speed down to 15 miles an hour and he accordingly cut his speed down until he passed a sign giving eight miles as the limit. He testified that at no time until he was stopped did his speedometer show more than 11 or 12 miles an hour. He was promptly acquitted.

How Automobiles Aided the Runners.

Although the message which Mayor McClellan, of New York, sent to Mayor Busse, of Chicago, "by bearer," was carried the entire thousand miles of the way on foot, the irrepressible motor car played an important part in the accomplishment of at least one stage of its travels. From Syracuse to Auburn, N. Y., three trucks, loaned by the H. H. Franklin Mfg. Co., carried 44 of the relay runners, dropping them one at a time to relieve others who were picked up at three or four minute intervals. Needless to say the freshness of the reliefs, not to mention the cheering influence of having the whole team present to witness the efforts of each individual, went a long way toward making that portion of the enterprise a successful one.

Hartford Contracts for an Ambulance.

Having rejected all bids for supplying an automobile ambulance to the city of Hartford, Conn., the police commissioners —to whose department the city ambulance service is attached— have given the contract to the receivers for the Pope Mfg. Co., without the formality of public letting. The contract price for the ambulance is $3,750, the figure submitted by the receivers in the original bid, but which was not the lowest. The new ambulance is to be a Pope-Hartford of 30 horsepower, with a wheel base of 130 inches. The body will be of the approved modern type incorporating side doors and having cots for four persons, all of which are compactly housed when not in use.

Tipping Off Motorists Offends Police.

When Percy Hollsworth, of 206 West 140th street, Manhattan, was arrested for speeding on Bay street, Stapleton, Staten Island, on Saturday, 25th inst., the police got from him a card on which was printed, "Do not speed here; police in plain clothes are watching you and you will be arrested." Hollsworth said the card was handed to him by a man at the St. George ferry, and the entire force on Staten Island was put on the lookout for the man who thus dared to warn motorists against fracturing speed regulations. Hollsworth had to put his diamond ring in hock at the station house to insure his appearance in court.

OHIO'S NEW LAW TO BE TESTED

Cincinnati Automobile Club to Join in Friendly Litigation—Question of Double Taxation the Main Issue.

What appears like double taxation to the Ohio automobile owners is to be subjected to a thrashing out in court. The constitutionality of the new State law is to be tested in a suit to be managed by Harry Probasco, of Cincinnati, attorney for the Cincinnati Automobile Club. Neither Mr. Probasco nor the members of the club seriously object to the State registration fee, but they do object to the additional imposition of local license fees under city ordinances. Mr. Probasco does not have much faith that the State law will be held to be unconstitutional, but since the suit is to be a friendly one all the way through, he has decided to raise the question as to the validity of the State law, while attacking the legality of the Cincinnati ordinance.

Missouri Law Indifferently Obeyed.

Missouri automobile owners have not been prompt to observe the requirements of the law enacted in 1907, only 3,000 having registered their machines with the Secretary of State. Chauffeurs are even more backward in the matter. The number of automobiles registered is regarded as a very small percentage. Secretary of State John E. Swanger has got his dander up and notice has been given that both owners and chauffeurs will have to toe the line before August 1st or be prosecuted. The law requires that chauffeurs shall be registered and receive badges which they are required to wear, displayed as a policeman does his star. The machine owners are required to send to the Secretary of State at Jefferson City detailed information as to their automobiles. The registration fee is $5, and this money goes to a fund for the improvement of roads.

Indianapolis Enforcing Its Shakedown.

Indianapolis authorities are after those automobile owners who have failed to pay their license fees for 1907 under the city ordinance imposing a local fee. More than 100 warrants, sworn out in November, 1907, have been placed in the hands of Patrolman Kerins, who thus far has succeeded in placing 15 recalcitrant owners before Judge Whallom. Each of the victims of the law was mulcted in a fine of $1 and costs. When the warrants were issued in November last automobile owners contended that the State law was explicit in declaring that the State license fee was the only fee that should be charged, and that they should not be required to pay the city license fee. A test case was instituted, and the city won on the ground that the ordinance was a police regulation and not a revenue tax.

The Week's Patents.

888,196. Igniter Mechanism for Internal Combustion Engines. Edwin Ruud, Pittsburg, Pa., and Conrad Regenbogen, Manchester, England, assignors to The Westinghouse Machine Company, a Corporation of Pennsylvania. Filed May 18, 1904. Serial No. 208,577.

1. In an internal combustion engine in combination with an inlet valve, a pivoted valve operating lever, a cam actuated rod for actuating said lever, a yielding connection between said rod and said lever whereby said rod is capable of further motion after said valve is closed, an igniter trip bar pivotally mounted on said rod, a stationary igniter terminal, a pivoted igniter terminal adapted to be moved into contact with said stationary terminal by said rod through the agency of said trip bar, an adjustable timing device for controlling the pivotal motion of said bar and releasing said movable terminal and means for forcing said movable terminal out of contact with said stationary terminal.

888,214. Tire for the Wheels of Road Vehicles. Jean V. F. A. Yberty and Emile B. Merigoux, Royat-les-Bains, France. Filed Aug. 9, 1906. Serial No. 329,907.

1. In combination, a wheel rim, tire support therefor of U shaped cross section provided with bolt holes, a tire composed of a plurality of distinct elastic units spaced apart from each other and provided with openings, tire bolts extending through said openings in said units and said support, said support being provided with slots, support bolts extending through said slots and between said units, wedge shaped blocks interposed between said units and forming therewith a continuous tread, block links loosely secured to said blocks and having slotted ends connected with said support bolts, and rim bolts connecting said support bolts with said rim.

888,225. Friction Gearing. James K. Cochran, Chicago, Ill. Filed Dec. 26, 1905. Serial No. 293,370.

1. In gearing of the character described, the combination with a shaft and a plurality of friction members thereon provided with a plurality of sets of friction faces, of a plurality of sets of adjustable friction wheels, one of said sets co-operating with each set of friction faces, and common actuating means for the various sets of friction wheels connected to the same for effecting their simultaneous adjustment.

888,226. Starter for Combustion Engines. Lembert C. Coppock, Marion, Ind., assignor to Coppock Motor Car Company, Marion Ind., a Corporation of Indiana. Filed April 4, 1907. Serial No. 366,366.

1. A plurality of combustion engine cylinders, means mounted in connection with each cylinder for starting the engine, a lever for controlling the starting mechanism for each cylinder, a rotary rod mounted in the means in which the levers for all of the cylinders are fulcrumed, eccentrics on said rods for actuating said levers, and means mounted on said rod for turning it by hand.

888,265. Power Transmission Mechanism. Norman Ruland, New York, N. Y.—Filed July 20, 1907. Serial No. 384,711.

1. In combination, two oppositely disposed rotatable discs, a friction wheel intermediate said discs and in engagement with the surface of each and movable along said surfaces to vary the relative speeds of rotation of said discs and said wheel, and means for applying fluid pressure to both of said discs to hold them in engagement with said wheel with equal pressure and to eliminate side thrust upon the wheel.

888,269. Cushion Tire for Road Vehicle Wheels. James Stevens, London, England. Filed March 26, 1906. Serial No. 307,963.

1. A protecting cover for resilient tires of wheels of road vehicles comprising an endless flexible band around the periphery of said resilient tire, a series of concavities in the periphery of the resilient tire, insertion pieces fitting in said concavities and located between said band and the resilient tire all round the latter to prevent creep, a series of protecting shoes of channel shape in cross section, and means to secure said shoes to the said band and insertion pieces —to thereby hold said shoes spaced apart in position over the said resilient tire and a band of flexible material such as leather or canvas located between the said insertion pieces and said resilient tire substantially as described.

888,282. Explosive Engine. Henry O. Westendarp, Saugus, Mass., assignor to General Electric Company, a Corporation of New York. Filed Nov. 4, 1903. Serial No. 179,771.

1. In an explosive engine, the combination with an explosion cylinder provided with exhaust and admission ports, and a power piston in the cylinder covering and uncovering said ports, of means for injecting a scavenging charge at substantially atmospheric pressure into the cylinder, through certain of the admission ports and means for injecting a charge of fuel into the cylinder through other admission ports substantially in continuity with the scavenging charge and at a definite point in the compression stroke of the piston after closure of the exhaust ports.

888,302. Wheel Tire. Frank N. Boughn, Riverside, Cal. Filed Oct. 29, 1907. Serial No. 399,660.

A vehicle wheel having a rim provided with a flattened tread surface and provided at one side of said surface with an integral annular flange, the said tread surface being formed at intervals with transverse grooves, a metallic tire having a flattened base resting against said flattened tread surface, said tire being engaged at one side of said flange, transverse ribs upon the flattened surface of the tire engaging the grooves in the rim, and a removable retaining flange at the opposite side of the rim engaging the opposite side of the tire and engaging and holding said ribs seated in the grooves.

888,345. Pneumatic Tire. Harry Musclow and William A. Roberts, Vancouver, British Columbia, Canada. Filed July 23, 1907. Serial No. 385,109.

1. As an inner tube for a pneumatic tire, the combination with an inflatable tube ring of flexible elastic air tight material, of a denticulated ring cemented round the tread of the tube on the inside and a corresponding denticulated ring on the diametrically opposite side of the tube the denticulations of the two rings interprojecting and the conformation of the inner cemented rings and the sides of the dentriculations approximating to the inner conformation of the tube before inflation.

888,347. Vehicle Spring. Michael M. McIntyre, Cleveland, Ohio, assignor to The Perfection Spring Company, Cleveland,

Studebaker

RECORD FOR JUNE

Perfect Score In the 24 hour endurance contest at San Leandro, Cal., under the auspices of the Frisco Automobile Club, a Studebaker "30" Model H stock car finished with a perfect score, and was the only contestant to run the entire 24 hours without stopping its motor.

Perfect Score In the Wilmington, Delaware, Sealed Bonnet Contest, held June 27th, a Studebaker "30" entered, finished with a perfect score.

Perfect Score In the Stroudsburg, Pennsylvania, Endurance Run, June 27th, the Studebaker "30" finished with a perfect score.

Studebaker Wins In the Hundred Mile Road Race at Portland, Oregon, June 4th, over a 14.5 mile course, the two Studebaker cars entered won first and second place in competition with ten other cars. The winning Studebaker covered the 100 miles in 2 hrs. 4 min. 8 sec.

Studebaker Wins June 27th, in the Hill Climb at Delaware Water Gap, Pennsylvania, the Studebaker made the mile climb in 2 min. and 2 sec., winning the event.

General Office, CLEVELAND, OHIO. Main Factory at SOUTH BEND, IND.

Digitized by Google

Ohio, a Corporation of Ohio. Filed June 2, 1906. Serial No. 319,814.

1. The combination, with the hangers or outriders of a vehicle, of an upper and a lower spring member clamped together to form a unitary structure, links or shackles extending upwardly from said hangers or outriders and connected to the ends of the upper spring member, and links or shackles extending downwardly from said hangers or outriders, the lower spring member terminating in scrolls, the ends of which are connected to the last mentioned links or shackles, substantially as specified.

887,691. Electrically Driven Vehicle. William B. Potter, Schenectady, N. Y., assignor to General Electric Company, a Corporation of New York. Filed June 25, 1903. Serial No. 163,088.

1. The combination with a trolley pole, of a universal joint cross swiveled thereto, a contact shoe lingitudinally pivoted on said cross, and means for yieldingly holding said shoe at an oblique angle to said pole and in a definite swiveled relation thereto.

887,701. Steering Gear. Charles J. Schoening, Honolulu, Hawaii, assignor of one-third to George P. Cooke, Honolulu, Hawaii. Filed May 4, 1907. Serial No. 371,773.

1. A steering gear for motor vehicles provided with a steering column made in sections telescoping one in the other, means in connection with the sections for preventing rotary movement thereof with respect to each other and a locking device for locking the sections in the adjusted position.

887,781. Transmission Device. Anton P. Fischer, Pittsburg, Pa. Filed Oct. 24, 1907. Serial No. 398,878.

1. A transmission device of the class described, comprehending a rotative cylinder of elliptic form in cross section, provided with oppositely disposed by passes communicating with the interior thereof and having an exterior annular extension about its axis of rotation, oscillatable valves in said by-passes, a sleeve carried by said extension and adapted to slide longitudinally thereon, means associated with said valves and sleeve whereby a sliding movement imparted manually to said sleeve will oscillate the valves, a rotative piston in said cylinder provided with oppositely disposed radial slots, spring actuated blades in said piston slots adapted to engage the walls of the cylinder, and a liquid filling the unoccupied space in said cylinder and by-passes.

887,824. Automobile Gearing. Lester V. Lochner, Auburn, Ind. Filed Oct. 14, 1907. Serial No. 397,383.

A gearing of the class described, comprising a drive shaft, a driven shaft geared thereto, the driven shaft having yokes secured at its outer ends, the yokes comprising vertically extending portions and outwardly and horizontally extending portions at the upper and lower ends thereof, the driven shaft having hemispherical gears at the outer ends, the teeth of the gears being arranged in circumferential rows upon the hemispherical faces, the teeth of the alternate rows being arranged between the teeth of the opposite rows, a second yoke mounted for angular movement with respect to the first yoke, the yoke having a shaft, a hemispherical gear carried by the shaft and arranged to mesh with the first named gear, and a steering apparatus connected with the last named yokes.

887,888. Carriage Cushioning Device. Melanie Wolf, New York, N. Y. Filed May 18, 1907. Serial No. 374,373.

1. In a motor vehicle, the combination with a motor, of a cushioning device comprising compressed air cylinders, spring plates secured to the axles of the vehicle and supporting said air cylinders, spring actuated pistons working in said air cylinders, and universal joints connecting the piston rods with the underframe of the vehicle, a compressed air receptacle communicating with the said air cylinders, an air pump supplying compressed air to said receptacle, a crank shaft to be operated from the motor and driving the air pump, and means to at a certain pressure automatically disconnect the air pump from the motor, substantially as set forth.

887,925. Shock Absorber. David M. Davis, Washington, D. C. Filed June 1, 1907. Serial No. 376,869.

1. A shock absorber comprising a cylinder having communication with the atmosphere, a piston in said cylinder, receivers, fluid passages from the cylinder to the receivers, return fluid passages from the receivers to the cylinder, non-return check valves for the first-mentioned passages, and regulating valves for the return passages.

887,961. Friction Transmission Mechanism. Byron G. Pfeiffer, Detroit, Mich. Filed July 11, 1907. Serial No. 383,165.

1. Transmission mechanism comprising a main shaft, a follower shaft in axial alignment therewith, a friction clutch adapted to directly couple the shafts, a conical friction drum on the follower shaft concentric with the main shaft, a friction cone reduction train adapted to operatively connect the exterior face of the drum with the main shaft, a reversing friction cone train adapted to operatively connect the interior face of the

drum with the main shaft, and means to throw said trains into gear.

887,988. Deodorizer for Internal Combustion Engines. William R. C. Wakley and Robert Parsons, London, England. Filed Dec. 14, 1907. Serial No. 406,558.

1. In a deodorizer for the exhaust gases of an internal combustion engine, the combination of a casing, a perforated water receptacle connected to a water circulating system, an inlet and an outlet for the exhaust gases so arranged that the said gases pass through the jets of water, a sump to receive the water, a filter, and a pipe connecting the sump with the said water circulating system.

888,074. Means for Starting Internal Combustion Engines. Giovanni Enrico, Turin, Italy, assignor to F. I. A. T. Fabbrica Italiana Automobile Torino, Turin, Italy. Filed Oct. 3, 1906. Serial No. 337,292.

1. In an internal combustion engine, the combination with the cylinder of inlet and outlet valves, cams for operating such valves, a hollow cam shaft carrying such cams, an additional valve adapted to admit compressed fluid to the engine for starting purposes, a cam for operating said additional valve, said cam being independent of the outlet and inlet valve cams, and being adapted to slide on said cam shaft, and a second shaft for operating the cam for the additional valve, said shaft extending within the cam shaft and being connected to its cam throcgh slots formed in the cam shaft.

888,195. Timer. Walter W. Robinson, West New York, N. J., assignor to Witherbee Igniter Company, a Corporation of New Jersey. Filed Aug. 24, 1907. Serial No. 389,973.

1. In a timer of the character herein specified, the combination with a hollow casing, contacts carried thereby, and a rotatable member located therein, of a spring-actuated roller carried by said member, and a loose ring having smooth inner and outer faces located between the roller and the wall of the hollow casing.

887,279. Odometer Mounting and Lock for Vehicles. Andrew J. Smith, Los Angeles, Cal. Filed June 10, 1907. Serial No. 378,111.

In a device of the class described, a revoluble vehicle wheel mounted on a stationary axle; an odometer having a stationary and a revoluble member, said stationary member being rigidly mounted on said axle and said revoluble member being rotatively secured to the hub of said wheel; a cylindrical casing for said odometer bolted to the hub of said wheel, the heads of the bolts projecting inside of said casing; and a screw cap for said casing adapted to be locked thereon.

887,295. Automobile Tire. Wilhelm Weidling, Magdeburg, Germany. Filed April 29, 1907. Serial No. 370,862.

An automobile tire having a cover of leather, a strip of leather around the outer circumference thereof, clip like holders on the same at regular intervals, metal blocks in said holders other metal blocks laid between the holders, both kinds of metal blocks provided with grooves forming together continuous grooves running around the circumference, flexible endless bands in said grooves all as described and for the purpose set forth.

887,356. Ball Bearing. Jackson L. Straub, Lancaster, Pa., assignor of one-half to Ernst Sachs, Schweinfurt-on-the-Main, Germany. Filed Nov. 14, 1906. Serial No. 343,414.

1. In a ball bearing, concentric bearing members having confronting grooves or ball races, an annular series of balls runing therein, and a ball spaces or separator consisting of an undulated ring of sheet metal passing in and out between adjacent balls throughout the series and having the balls seated alternately in the pockets of the two sides of the ring formed by the concavities of the undulations themselves.

887,370. Carburetter. Alexander Winton and Harold B. Anderson, Cleveland, Ohio, assignors to The Winton Motor Carriage Company, Cleveland, Ohio. Filed June 23, 1906. Serial No. 323,117.

1. A carburetter, comprising means for maintaining a fluid level, an air passage having its lower wall projecting into said level to form a fluid holder, said wall provided with a fluid orifice in a plane below said fluid level, the orifice so restricted as to require spray action from said orifice within the air passage for increasing fluid supply to the increased volume of air passing therethrough.

887,413. Speed and Power Controlling Mechanism. Louis J. Monahan, Oshkosh, Wis., assignor of one-third to J. D. Termaat and one-third to M. L. Cottrill, Oshkock, Wis. Filed June 12, 1905. Serial No. 264,972.

1. In power transmitting mechanism, the combination of a rotatable power transmitting shaft, variable speed transmitting mechanisms loosely mounted on said shaft, clutch mechanisms rotatable with the shaft but slidable thereon, levers for effecting the engagement of the clutches with the respective variable speed transmitting mechanisms, cylinders arranged in suitable position with relation to the levers, and pistons connected to the levers and operated by an actuating medium admitted to and exhausted from the cylinders and adapted, when the piston of any cylinder is moved in one direction by the actuating medium, to cause the lever relating thereto to operate its clutch to effect a clutching engagement with its associated transmitting mechanism, and means, when the actuating medium is exhausted from the cylinder, to cause the lever

PANHARD OIL

"The Oil in the Checkerboard Can"

Is the one perfect automobile lubricant. Panhard Oil is the only cylinder oil made that will lubricate at all temperatures. It insures against pre-ignition, pounding, and other costly engine troubles which are commonly caused by poor cylinder oil carbonizing in the cylinders.

The new Sealed Can protects you against the substitution of an inferior oil—always see that the seal is not broken.

and consequently the piston to return to normal position.

887,505. Air Cushion and Air Compressor for Automobiles and Other Vehicles. Wesley H. Nelson and Lee W. Galloway, Norwood, Colo. Filed May 27, 1907. Serial No. 375,950.

1. A vehicle having an air compressing apparatus comprising a plurality of double acting air pumps mounted upon the wheel axle and having the rods of their pistons connected to the bottom of the vehicle, and air reservoir fixed to said vehicle bottom, an arrangement of pipes having communication with the cylinders of said pumps opening above and below the pistons of said pumps, and means delivering air pressure from said arrangement of pipes to said air reservoir.

887,551. Vehicle Brake. Herbert M. Vanderbilt, Suffern, N. Y. Filed Aug. 1, 1906. Serial No. 328,753.

1. In a vehicle brake, clamping means adapted to engage the wheel of the vehicle when thrown in contact therewith, means attached to said clamping means designed to be drawn under the wheel when said clamping means and wheel are engaged, means for automatically returning said clamping means and the means attached thereto to an elevated position when the wheel is backed off of said last named means, and means then operating to automatically withdraw all of said means from the wheel.

887,562. Vehicle Wheel. Martin L. Williams, South Bend, Ind. Filed Dec. 26, 1905. Serial No. 293,291.

1. The combination with a vehicle axle and a terminal yoke upon the latter, of a spindle member pivotally connected with said yoke to oscillate upon an axis substantially perpendicular to the longitudinal axis of the axle, a wheel journaled upon said spindle member and a guard mounted to move with said spindle member during the oscillatory movement of the latter and overlapping the contiguous portion of said yoke which supports the spindle member, the overlapping portion of said yoke guard being internally spherical and the exterior of the overlapped portion of the yoke of corresponding shape.

887,567. Flexible Metallic Vehicle Wheel. Gustav Auberlin, U. S. Navy. Filed April 4, 1907. Serial No. 366,294.

1. A vehicle wheel comprising a hub, yielding spokes, and a rim composed of an inner and outer series of flexible cables and means for spacing them apart.

887,633. Internal Combustion Engine. Samuel H. Heginbottom, Frank H. Heginbottom, and Walter G. Heginbottom, Saginaw, Mich. Filed Dec. 2, 1907. Serial No. 404,667.

1. The combination with a cylinder having an inlet port and a piston adapted to open and close said port, of means for adjusting the cylinder and piston, one relative to the other to vary the amount of charge admitted to the cylinder through the inlet port.

887,684. Vehicle Wheel Tire. Henry H. Moore, Paris, France. Filed Sept. 22, 1906. Serial No. 335,732.

1. An elastic tire for vehicle wheels comprising, in combination with a felly; metallic sections inserted one in the other all around the felly; means for preventing the sections from falling out of said felly and springs, each working conjointly on two sections at a time and tending to elastically force the sections outwardly to the periphery of the felly, substantially as and for the purposes described.

887,179. Wind Shield. Charles F. Brandt and Walter R. Johnston, Columbus, Ohio. Filed April 26, 1907. Serial No. 370,510.

A wind shield comprising a lower sash, bracing means supporting the same, a channel secured at each side of said sash and being of greater width than the thickness of said sash, a channel member hinged upon the said channel, an upwardly extending flange formed along the upper edge of said sash, a second sash adapted to be positioned upon said first sash and having its lower side in engagement with said flange and its ends positioned in said hinged channel, a set screw mounted in said hinged channel member and adapted to force said second sash into secure engagement with a wall of said hinged channel member, said second sash being adapted to be moved laterally in said channel and lowered in said channel to the side of the first sash, said hinged channel member being adapted thereupon to be folded laterally to embrace the upper edges of said sashes, said set screw being adapted to be inserted at the same point of said hinged channel member to force said sashes into secure engagement.

887,180. Controller. Charles O. Barnes, Oswego, N. Y., assignor to Barnes Gear Company, Oswego, N. Y. Filed March 23, 1907. Serial No. 364,178.

1. The combination with a tubular support, controller rods mounted therein and a head secured to said support, of operating levers secured to the respective controller rods, and friction devices located between said levers and the head.

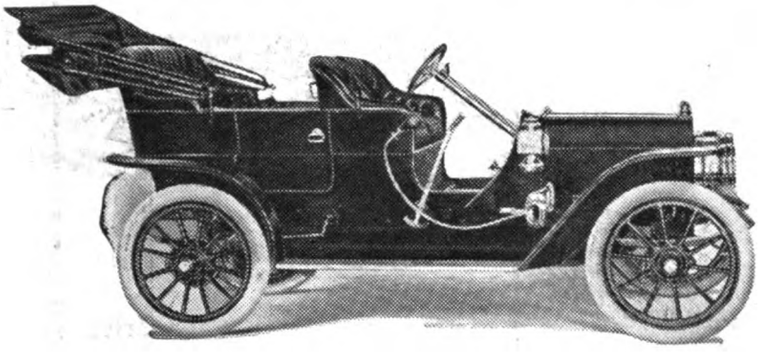
Warner Auto-Meter

GUARANTEED FOR ONE YEAR.

"Thirty Days' Free Trial"

When a manufacturer is willing to send his product to anyone, anywhere, for 30 days—with no deposit, no agreement to buy, no promise to do anything except give that product a fair trial—he must have more than ordinary confidence in his article. In order for him to have that confidence he must have a most extraordinary product.



That's what we do. We'll send an Auto-Meter to any automobile owner in the country—with no deposit, no agreement, no promise to do anything but put it on his car and give it a fair trial. It doesn't matter whether he has another make of speed indicator already on the car or not. Indeed, for the sake of comparison, we hope he has. We will abide by the decision—for he will always keep the indicator that tells the truth. We claim for the Auto-Meter that it is the only one of which "the dial never lies." We believe that the instrument itself is the most eloquent salesman we have—we're willing to let it do our talking. Send to-day—just tell us what make and model of car you have—size of tires, etc.,—and we will send you an Auto-Meter.

Is Right Stays Right Accurate At All Speeds

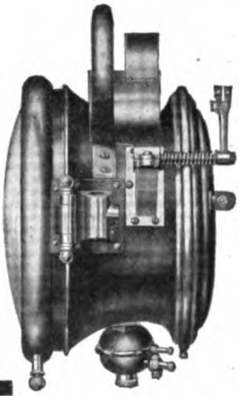
SOLARCLIPSE LAMPS



SOLARCLIPSE
DOUBLE RAY LAMPS

are produced under the patented Besnard System of Light Eclipsing. It is now generally admitted that these lamps definitely solve the acetylene head light problem.

The driver of the car controls the light at all times.

Two distinct rays are projected from Solarclipse Lamps—one powerful long distance field of light which penetrates the darkness for over 1,000 feet, and one short distance ray which is thrown directly in front of the car. Through the simple manipulation of a dash-board switch the long distance ray may be cut off or eclipsed at will.

Complete description in our 1908 catalog.

How Much Do You Pay to Keep Your Automobile Running?

Ten Winton Sixes Ran 65,687.4 Miles at an Upkeep Cost of $1.00 For Each 4,343 Miles

WINTON SIX

High-grade automobiles average 3,500 miles a season, and cost for upkeep—well, inquire of the man who pays the bills.

Ten Winton Sixes ran 65,687.4 miles in six months (up to June 30, 1908), and cost for upkeep all told $15.12½.

That's 25 cents per month per car.

Or $1.00 upkeep for each 4,343 miles.

These figures are proved by the sworn reports of the ten individual owners of these cars. Glad to send you their affidavits if you like.

Must be an exceptional car to do 4,343 miles on $1.00 upkeep.

Winton Six owners think so, because they pay the bills. So we are making the same exceptional car another year.

Same high-grade quality throughout. Same 48.6 horsepower, six-cylinder motor. Same Eisemann magneto. Same carburetor. Same system of lubrication (one Winton Six ran 242 miles on one quart of oil in the Long Island Endurance Test). Same cooling system. Same selective, sliding gears. Same superb multiple disc clutch. Same springs, axles, frame. Same safety auxiliary gasoline tank.

And the same self-starter. A starter that starts. Take your seat, press a button, and the motor runs.

The Winton Six carries its starting crank in the tool box, because it isn't needed elsewhere.

Own a Winton Six and end your humiliating work of cranking.

The five-passenger body is new, and the design is beautiful. Don't take the picture as proof, but see the car itself.

Then ride in the Winton Six. That's convincing. Quietest motor you ever saw. Sweeter than electricity, flexible as steam, and wonderful on hills. Makes hitherto bothersome grades ashamed of themselves. Cuts down gear changing, because it goes through traffic and up the hills on high gear. Saves gasoline, wear and tear, tires, and patience.

These are six-cylinder times.

And you haven't even the excuse of higher first cost to deny yourself the best there is in automobiles; because the Winton Six sells at $3,000, and represents a saving on first cost and on after-cost (upkeep)—a substantial saving that no business man, however wealthy, can afford to disregard.

Our complete and unusual catalogue is ready. Throws new light on six-cylinder cars, and is worth the time of any man or woman who reads it. Also let us send a booklet detailing our $2,500 prize plan to benefit owners.

Drop us a line to-day.

THE WINTON MOTOR CARRIAGE CO.
Cleveland, Ohio

Winton branch houses in New York, Boston, Philadelphia, Baltimore, Pittsburg, Detroit, Chicago, Minneapolis, Seattle and San Francisco. Winton agencies in all important places.

$3000 is the price of the 48.6 h. p. Winton Six, the 4,343-Miles-on-$1-upkeep car. For buyers who want more power, we are making a 60 h. p. Winton Six, with 7-passenger body and four-speed transmission. This car will be ready for early fall delivery and will sell at $4500

Large Sales

make it possible for us to import **THE CELEBRATED BRAMPTON CHAINS** from **ENGLAND** (paying freight and duty), and sell them at the same price at which the several other automobile chains are sold to manufacturers, jobbers, dealers and users.

THE BRAMPTON MOTOR CHAIN

All side plates on both sides on the Brampton Chain are stamped **"BRAMPTON."**

LARGE SALES and SMALL PROFIT with thousands of satisfied customers is our best advertisement.

THE BRAMPTON CHAIN is made of helf-hardening Steel; the strongest Chain in the World. All parts polished; fits sprockets (that are properly cut) without friction.

Some of the other chains may look like **THE CELEBRATED BRAMPTON CHAIN** because some of the other chain makers began to copy the design and shape of the **BRAMPTON CHAIN** links in 1904. They have improved somewhat on their copied design from time to time until these chains now look more like the **BRAMPTON CHAIN** than ever before. These chains somewhat resemble the **BRAMPTON** in appearance, but the manufacturers of such chains have been unable to copy the material—self-hardening steel.

NO CHANGE IN THE BRAMPTON

There has been no change in the design, construction, material or finish of the **BRAMPTON MOTOR CHAIN** in the past ten years.—**"ENUF SED."**

PRICE

The price being equal, it's presumable you want the best, and full value for your money. In such cases, the **BRAMPTON FILLS THE BILL,** and the prices are the same to manufacturers, jobbers, dealers and consumers as any other chain of equal size—as follows:

CHAINS TO FIT AMERICAN CARS

1 x ⅜ x 9-16—1 x ½ x ⅝—1 x ½ x 9-16 roller	$1.00 per foot.
1 x ⅝ x ⅝ roller	1.17 "
1¼ x ½ x ⅝—1¼ x ⅝ x ⅝—1¼ x ⅝ x ¾ roller	1.25 "

We also carry in stock the **BRAMPTON CHAINS** to fit Foreign Cars—Mercedes, Panhard, Martini, Fiat, etc.

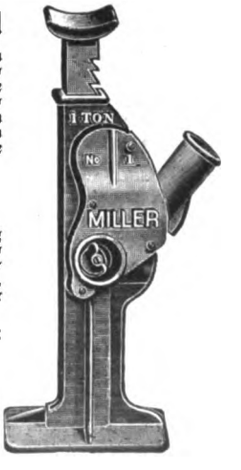
Your 1908 Car

You can have the new car that you order fitted with the **CELEBRATED BRAMPTON CHAIN** if you order it that way. No extra cost to either you or the manufacturer. All standard sizes in stock to fit American and Foreign Cars at the same price as the other chains.

SPECIAL CHAINS TO FIT THE INDIAN MOTORCYCLE.

Agents wanted in unoccupied territory. Catalog on request.

We are Sole American Agents for **BRAMPTON CHAINS,** and they cannot be bought from anyone else except through our Agents.



Pan-American Automobile Body Polish

Pan-American Polish was awarded the Bronze Medal at the Louisiana Purchase Exposition at St. Louis, 1904. This polish has been carefully prepared for the Automobile trade. It is also applicable to the carriage trade, or can be used on any varnished furniture or woodwork of any kind. It will remove stains, cover scratches; leaves the automobile with its original new lustre, without being sticky or greasy. Furnished in eight-ounce bottles. Guaranteed not to harm the finest varnish. For sale by all Automobile Dealers. Price 60 cents per bottle.

The Miller Automobile Jack

The Miller Automobile Jack is a quick acting, automatic lowering jack, designed especially for automobile use, and is adapted to the factory or garage as well as to be carried as a part of the equipment on motor cars. It is high-grade and one of the finest finished jacks on the market. We guarantee this jack for twelve months. The list price of the Miller Jack, $3.50 each.

Mayo Radiators Make a Good Car Better and Their Use on a Car is a Hall-Mark of Quality.

¶ Mayo Radiators are made in a quality shop. In their construction no expense is spared, no crude methods obtain. In their use complete satisfaction results.

¶ Mayo Radiators perform their functions well under all conditions—and conditions at times are exacting. It is at just such times that Mayo quality asserts itself.

¶ The engineer can eliminate possible radiator troubles from his calculations by the adoption of the best possible radiator. The test of years and use has proved that we make it.

¶ Our capacity limit on new contracts is rapidly being reached.

MAYO RADIATOR COMPANY, New Haven, Conn.

BEAR IN MIND

that in eight years there have been five models of Stevens-Duryea Cars. Worked out to perfection before being placed on the market — their mechanical features distinguished for being ahead of the times and because of common sense construction. Contrast the evolution of five unqualifiedly successful Stevens-Duryea Models with the every few months "improvement," radical changes, etc., in the output of some motor factories.

WHEN YOU BUY A STEVENS-DURYEA CAR YOU SECURE A MINIMUM OF UPKEEP EXPENSE AND A MAXIMUM OF PEACE OF MIND.

WRITE FOR DESCRIPTIVE MATTER

DOW TUBES Are the Most Economical

(The Best Tubes Ever Manufactured)

The Faithful Record Given Below by C. C. Scrivener, Driver for Oakleigh Thorne, Esq., of New York, Shows that ONE DOW TUBE SAVED $127.49 IN 4½ MONTHS.

Dow Tire Co., 2000 Broadway, New York City. July 22, 1908.

Gentlemen—Having had up to date such fine service out of your "Dow" tubes on the Packard Runabout, I consider it only fair to tell you and the public how good they really are. One year ago, on July 17, 1907, I put in four of your tubes.

On October 5, 1907, the right rear tube, owing to a defective valve, had to be removed. The left rear was not removed until a few days ago on account of a bad blowout, the right front a few days later blew out, both owing, I believe, to old shoes. The left front is still doing service and is as good as ever.

Now comparing the rear shoes and tubes. After removing the right one on October 5, 1907, I did not put in a "Dow," but took it as a good chance to compare plain tubes with the "Dow." In this shoe I used in four months and two weeks eight tubes and three shoes against one "Dow" tube in two shoes.

As soon as our plain tubes in the other two cars are used up I intend to put in "Dow" tubes all around; their showing on the runabout under all conditions of roads, heat and cold, is entirely satisfactory. As to ordinary punctures, I don't know what they are any more. Nothing but a bad blowout will finish a "Dow" tube. Even a four-inch cut has not caused me any trouble on the road. I rode a shoe with such a cut containing a "Dow" tube for three weeks, then changed shoes just because it was the right thing to do.

I will cheerfully tell any one who wishes to know all I know about your tube.

Trusting you have many others as pleased as I am, I remain,

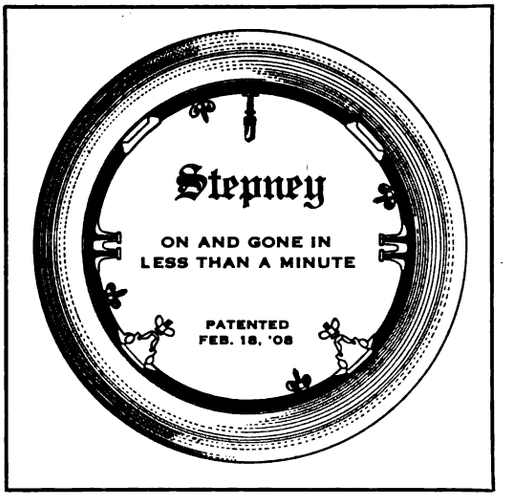
Respectfully yours,
C. C. SCRIVENER, Driver for Oakleigh Thorne, Esq., New York.

ONE YEAR'S CONSTANT SERVICE IN THE BOSTON FIRE DEPARTMENT.

Headquarters Fire Department, City of Boston, Bristol Street,

Dow Tire Co., New York, N. Y. Boston, July 20, 1908.

Gentlemen—Having used the Dow Non-Deflation Tubes since August 19, 1907, on the automobile used by Chief Mullen of this city fire department in his response to alarms of fire, I feel that, in return for the excellent results received from these tubes, I ought to inform you of same. Several persons have inquired of me as to their merits, and I have always spoken in the highest terms of them, but never felt that I could write you confirming my statements until such time as they had been in use for about a year.



We have given them all kinds of tests, and will truthfully say that they have withstood all punctures, and with the exception of "blow-outs," which are liable to occur with any type of inner tube, they have given excellent satisfaction.

Trusting this letter may be of benefit to you, I remain,

Yours very truly,
(Signed) JOSEPH A. WEBBER, Lieut., Aide to Chief.

STEPNEY
Spare Motor Wheel

The only cure for tire troubles. Get one and be up-to-date. There is only one genuine spare wheel—"The Stepney." (Beware of imitations.)

DESCRIPTION—The Stepney Spare Motor Wheel is a device the adoption of which will serve to obviate the tire troubles experienced in motoring. It is simply a standard clincher steel rim, without hub or spokes, having four clamps (two stationary and two adjustable) for securing it to the rim of the injured wheel. The Stepney is intended for your Spare Tire to be carried upon it fully inflated and ready for use. Any standard clincher tire can be used.

Write for Catalog B, explaining and illustrating the Stepney Spare Wheel in each and every detail. A postal card will do.

The Mitchell

The car you can afford to buy and KEEP

$2000

The Mitchell appeals **to you,** Mr. Business Man, because it gives you just as much **pleasure**—just as much and as **good service,** is just as **stylish** and neatly **finished** as any car, and doesn't cost you a small fortune to **buy**—or **keep.**

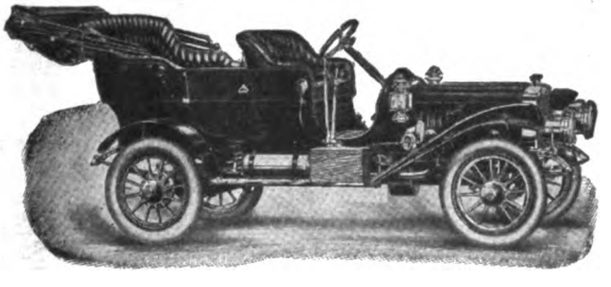
The Mitchell at $2,000 is the standard automobile value.

Prove it—Mr. Business Man.

Get **demonstrations** of the extravagantly high-priced cars—and then try the **Mitchell** over the **same** route.

The Mitchell agent will be glad to take you out if you're interested for 50 or 100 miles any time you say. Call him up (it places you under no obligation)—**Challenge** him—

Just say, "Show Me."



He'll come around with a car and show you a "silent argument" that will get your order or he will retire without a word.

Our catalog No. 18 is fully descriptive of the Mitchell 1908 Touring Car $2,000—Limousine $2,800—Roadster $1,250, and Runabout $1,000. Write for it—we'll also send letters from users, proving the Mitchell to be the most economical car to **operate.**

Mitchell Motor Car Co., 285 Mitchell Street, Racine, Wis.

Standard Manufacturers, A. M. C. M. A.

This car—shown here—35 h. p., 4 cyl., speed 50 miles, finished in Mitchell blue—price $2000—is excellent throughout—the car you ought to have at the price you ought to pay.

THE INCOMPARABLE WHITE

THE CAR FOR SERVICE

Write for White Bulletin No. 15

The above illustration is reproduced from the new White Bulletin No. 15, an attractive little booklet devoted to some of the more important automobile events of the last few months. The leading articles are "The New Road Record Between San Francisco and Los Angeles," "The Fort George Hill Climb," "The Quaker City Reliability Contest" and "The Harrisburg Reliability Contest." In addition to these four detailed accounts of White victories, brief space is given to the numerous minor contests in which the White has carried off first honors; also, the activities of private owners of White cars and the doings of "Government White Steamers" in this and other countries receive attention. We believe that you will find this booklet of interest.

YOU can do all kinds of work with this car as a handy Runabout without the tonneau; then put the tonneau on and take your family or friends for a ride in a roomy Five-Passenger Touring Car.

Many exclusive features make it the most remarkable two-cylinder car in this country selling at $1,400.

The powerful engine makes it a hill climber; the long wheel and full elliptic springs provide great comfort; you glide over rough roads without a jar.

It is easy to care for and always clean because of the few moving parts and the enclosed power plant, impervious to dirt, mud and water, and oil tight with proper lubrication.

Immediate access to every working part is provided. The low cost of maintenance is due to simple construction, small fuel and oil consumption and protection of parts against injurious road material.

WANT A BETTER PRICE ON SPACE

Motor and Accessory Manufacturers Meet at Atlantic City—Would Force Concessions at Chicago Show.

As the result of a two-day session at Atlantic City, which was held on Thursday and Friday of last week, July 30 and 31, the Motor and Accessory Manufacturers, Inc., has as a body decided to take the stand that its members will not exhibit at the Chicago show unless the management grants a lower rate for space or gives a larger rebate. It will be recalled that last year, after much delicate negotiation, the association was able to report to its members that it had obtained a rebate of 15 cents a square foot, a victory in economy which was somewhat neutralized when the management later announced the price of space and disclosed that it had been raised just 15 cents a square foot, from 75 cents to 90 cents. Comparing the price at Chicago with the net prices for space at the New York shows, where the members of the M. A. M. through their association get substantial discounts and percentage rebates, it is thought by the accessory people that the Windy City figure is too high and they therefore decided upon an ultimatum to reduce it. The association got about $9,000 in rebates from the New York shows last season, and only about $2,000 from the Chicago show.

The show committee of the M. A. M., consisting of Messrs. Raymond, White, Post, Byrne and Castle, held its session on Thursday and prepared its report for presentation the next day to the main body of the membership. The board of directors also had a meeting to transact routine business. Attorneys Allen and Graham, of the National Grange, appeared in behalf of that body to interest the M. A. M. in contributing financially to the good roads movement with which the Grange is identified. Decision was reserved as to what support, if any, would be given by the association as a body.

On Friday the report of the show committee, recommending that the members refuse to exhibit at Chicago unless the rate were lowered, was presented to the consideration of the association as a whole, and was adopted almost unanimously. Another feature of the day was a speech by W. B. Lasher, of the Weed Chain Tire Grip Co., on the subject of price cutting and its evils. Lasher appealed for vigorous action on the part of the association against price cutters. Suggestions were made as to the compiling of a list of bona-fide jobbers, but no action was taken in this direction. The Hedgeland Mfg. Co., of Canton, O., was admitted to membership. About 40 members or less than one-fourth of the total, attended the meeting.

Weed and Parsons Sue on Non-Skids.

Injunction proceedings have been brought by the Weed Chain Tire Grip Co. of New York, and the Parsons Non-Skid Co., Ltd., of London, England, against the Todd Rubber Co., of New Haven, Conn., to restrain it from marketing tire chains. The action was brought in the United States court in Hartford, Conn., and infringements against the patents of both plaintiffs are alleged.

Shanks to be Stearns' Sales Manager.

Charles B. Shanks, formerly advertising and sales manager of the Winton Motor Carriage Co., of Cleveland, is to be the sales manager of the F. B. Stearns Co., also of Cleveland. Upon resigning from the Winton company, Shanks took the northern Ohio agency for the Chalmers-Detroit which he is running as an individual enterprise.

Close Aurora Plant for Creditors.

The liabilities of the Aurora Motor Works, of Aurora, Ill., against whom a petition in bankruptcy has been filed, are estimated at $30,000 while the assets are calculated at $10,000. The constable has closed the factory in behalf of employes who have wage claims aggregating about $900.

AGREE ON ONE SHOW AT CHICAGO

Threatened "Independent" Project Abandoned—Accessory Makers Hesitate to Demand Price Concession.

Chicago show matters had a clarification on Wednesday so far as the car exhibitors were concerned, and the grievances of the American Motor Car Manufacturers Association were all placated so that there will be no "independent" or second Chicago show; but the demands of the Motor and Accessory Manufacturers, Inc., for more price concessions and the unwillingness of the show management to grant them has precipitated a real "situation."

At the meeting of the show committee of the National Association of Automobile Manufacturers the ultimatum of the accessory makers to the effect that they would refuse to exhibit at Chicago unless given a better price than 90 cents per square foot with a 15-cent rebate, was not officially delivered, although D. J. Post, of the accessory makers' show committee, was present with a copy of the M. A. M. Atlantic City resolution, ready to be presented at the proper time. Upon seeing the committee from the American Motor Car Manufacturers Association about to go into session with the N. A. A. M. show committee, Post refrained from any definite action in the matter until it would become clear as to whether the differences between the various bodies of car makers would be patched up and whether there was a likelihood of an "independent" Chicago show. The official proceedings of the day, however, went their course without the ultimatum being offered.

An informal gathering later, gave Post the opportunity to express the position taken by the Motor and Accessory people and to deliver their ultimatum in an unofficial way and, further, to hint at a show of their own. In an equally unofficial way it transpired that the Chicago management

Digitized by Google

is indifferent to the ultimatum, the N. A. A. M. show committee having at a meeting some little time ago decided that the price given the M. A. M. was the lowest that would be made, and that the space could readily be sold to other exhibitors at a greater profit. Not only are jobbers and unattached accessory makers anxious for the space, but the manufacturers of motorcycles are clamoring for an opportunity to exhibit. The withholding of the ultimatum on the part of the M. A. M. still gives that body the opportunity to recede with good grace from the position it decided at Atlantic City to take, but in case its demands are pushed there is every prospect of a clash.

A new method of show allotment was agreed to as being satisfactory, by Messrs. Benjamin Briscoe, H. O. Smith, R. M. Owen, J. B. Bartholomew, and General Manager Alfred Reeves, of the A. M. C. M. A., in conference with the show committee. The exhibitors are to be divided into classes, the considerations of preference being membership in the N. A. A. M., seniority in the number of earlier shows participated in, membership in either the A. L. A. M. or the A. M. C. M. A., etc. All the acts and agreements of the show committee were later in the day approved by the executive committee of the N. A. A. M., the meeting being attended by S. T. Davis, Jr., W. T. White, Charles Clifton, Thomas Henderson, W. E. Metzger, Benjamin Briscoe, H. O. Smith, L. H. Kittridge, R. D. Chapin, W. M. Lewis, and S. A. Miles, and as members of special committees, M. J. Budlong and G. W. Bennett.

A special committee presented a report and samples of a standard rim which has been pronounced satisfactory, and recommended its adoption subject to satisfactory commercial details. Sanctions were granted for the "Independent" show at Grand Central Palace the first week in January and for the Licensed show at Madison Square Garden the third week in January.

Velie Vehicle's Ambitious Plans.

Contracts for the reinforced concrete factory of the new Velie Motor Vehicle Co., of Moline, Ill., have been let. It is announced that the capacity of the plant will be 5,000 cars a year, the leader to be a buggy type machine with modifications that will in many respects make it resemble the more usual automobile models. Major L. M. Fuller will be factory manager, and considerable factory talent will be drawn from the Velie Carriage Co.

Death of Panhard, the Pioneer.

Rene Panhard, organizer of the Panhard-Levassor Company, died last week. He was 67 years of age, and although he had retired from active business management was still on the board of directors of his company. His last public apearance was at the dedication of the monument erected in Paris to Levassor, his former partner.

TIRE MAKERS HOLD A CONFERENCE

Lively Session Over Plan to Reduce Tire Cost to the Consumer—Discuss Uniform Discounts.

Those tire makers who are members of the Motor and Accessory Manufacturers, Inc., held a meeting at the Waldorf-Astoria, New York, on Saturday last, to hear the report on the results of a very remarkable letter which, over their signatures, had been mailed to six thousand automobile and accessory dealers. The letter asked expressions of opinion from the dealers as to the advisability of a reduction of list prices and discounts on tires in order to minimize if not eliminate the evils of price cutting, and at the same time urged the dealers' co-operation to that end. The tire makers were to have listened to the returns from this letter at Atlantic City, in connection with the meeting of the main body, but it was later thought advisable to hold a separate and special meeting in New York because of the importance of the subject.

The session at the Waldorf was both interesting and animated. Preceding the roll call, Chairman H. E. Raymond amiably remarked on the presence of a Motor World representative in the corridor downstairs, adding that those present would all doubtless be able to read a report of the meeting in detail in the Motor World, as usual, and from then on there was not a dull moment. To the 6,000 letters sent out, replies had been received from less than 1,200, or in exact figures, just 18.4 per cent. Of these replies an overwhelming majority were heartily in favor of the proposed plan, which involves in no way anything that could be termed a price agreement, in the usual sense, as each concern is left perfectly free to set its own list prices, though in all probability all list prices would be lowered under the proposed scheme.

The main idea is to reduce the cost of tire up-keep to the automobile owner, and by a uniform discount of some such slim figure as 15 per cent., make impossible the thriving business of cut price concerns and divert the renewal business to the legitimate dealer to whom it properly belongs. To make such a plan sucessful the support of a majority of the dealers is, of course, essential.

In considering the responses received by mail, the point was made that whereas the dealers in favor of the plan would naturally say so, those who were lukewarm or distrustful, if not openly hostile, would hesitate about committing themselves in writing and the silence of so large a proportion would seem to make their attitude open to question. On the other hand, it was urged that the assurances of support and co-operation from the Association of Licensed Automobile Manufacturers and from the American Motor Car Manufacturers' Association, at whose request the matter of reducing tire cost to the consumer was first taken up, were a sufficient guarantee of the favorable attitude of the majority of the dealers.

After a letter from a prominent automobile manufacturer had been read, commending the proposed action and setting forth the claims of the reputable dealers and the poor consumers, and while the discussion was at its height, one skeptical member of the assemblage, "foolish like a fox," slipped quietly from the room and used the telephone. He shortly marched back to the meeting again and announced, somewhat to the discomfort of the chairman, that he had just called up the local branch house of the solicitous maker and without being known had received quotations with a big discount on two well known makes of tires, one of which was—well, a smile went the rounds when it was mentioned.

On the proposition that lists and discounts should be lowered and the dealers thereby protected and the consumers benefited, all the makers were apparently in perfect accord. But when it came to a matter of absolutely uniform discounts, things grew very lively. It was the smaller makers and the late comers in the field who questioned the wisdom of "tying themselves up" in a position which appeared to them to place them at a disadvantage. "Some tires are demanded; others have to be sold," was the gist of the argument, and it was maintained that discounts should permit the making of special inducements, if necessary.

Having struck this obstruction, consisting of the opposition of some of the makers to an absolutely uniform discount feature, the plan was not ripe for immediate adoption, and so it was agreed to carry it over to another meeting. This latter is to be held in Cleveland on August 11, at which time the tire makers will buckle down and see what can actually be accomplished.

Dale Leaves a Large Estate.

The will of Charles H. Dale, the deceased president of the Rubber Goods Mfg. Co., has been filed in the Westchester county surrogate's office, at White Plains, N. Y. It lists an estate of $2,500,000, all of which goes to his wife, Jennie L. Dale. No bequests are left to his relatives or employes. It is said that he gave considerable property to them before he died.

Grossman Goes in for Himself.

Joseph Grossman, for the past two years or more the manager and treasurer of the National Sales Corporation, has resigned. He will go into business for himself.

Hopkins Resigns from St. Louis Car.

L. A. Hopkins, manager of the St. Louis Car Automobile Company, of New York, has resigned his position. The resignation takes effect immediately.

YEAR'S EXPORT TOTAL DECLINES

June Completes the Fiscal Twelve Months with a Slight Loss—The Record in Detail.

June completing the fiscal year of the export record, the figures for the twelve months show that $5,277,847 in American cars and parts were exported, as against $5,502,241 for the preceding year. The number of machines sent out during the period was 2,477 as against 2,862 for the year ending June, 1907, the sums represented by the cars alone being respectively $4,656,991 as against $4,890,886. The shipment of parts was a little heavier for the year just past, however, the sum being $620,856 as against $611,355.

For the whole year through the United Kingdom proved the best customer for American cars and parts, its purchases amounting to $1,796,509 as against $1,530,304 for the preceding year. British North America, the next best customer, shows a decline, its total being $951,386 as against $1,175,334. France, "the home of the automobile," shows an increasing inclination to buy American cars, being third on the list with a year's total of $692,365 as against $512,524. Germany, too, shows an increase, as do the West Indies and Bermuda, South America, "Other Asia" and Oceania, and the group described in the list as "Other Countries."

The month of June discloses losses in eight of the fourteen divisions. The United Kingdom heads the list of those on the wrong side, but both France and Germany have gains for the month. Mexico's purchases for the month amounted to less than half of what they did in June of 1907, dropping from $49,989 to $2,491, while South America dropped from $19,641 to $6911, or about a third. The total for the month was $710,722 as against $732,054 for June, 1907.

The summary in detail is as follows:

	June		Twelve Months Ending June		
	1907	1908	1906	1907	1908
Automobiles and parts of—					
*Automobiles	$669,570	$648,267	$3,497,016	$4,890,886	$4,656,991
Parts of	62,484	62,455		611,355	620,856
Exported to—					
United Kingdom	310,632	293,003	948,995	1,530,304	1,796,509

* Number not stated prior to July 1, 1906.

In the Retail World.

A new selling branch of the Atlantic Motor Car Co., of New York, is to be opened in Newark, N. J., for the sale of Stoddard-Daytons. A large building at 2228-2239 Halsey street is being erected for the purpose.

Ralph E. Brown, formerly of the Winton branch in Cleveland, has succeeded O. L. Gooden as the Winton agent in Buffalo. He will handle Winton Sixes exclusively and has secured a Main street location in automobile row.

The Michelin Tire Co., of Milltown, N. J., has opened a branch at 2001 Euclid avenue, Cleveland, O. R. B. Tracy has been appointed branch manager and D. K. Dickinson, formerly of the Hartford Rubber Works, will act in the capacity of assistant manager.

The Week's Incorporations.

Vincennes, Ind.—Webb Motor Fire Apparatus Co., under Indiana laws, with $100,000 capital. Corporators—Albert C. Webb, Joplin, Mo., and others.

Philadelphia, Pa.—American Pneumatic Motor Co., under Delaware laws, with $1,000,000 capital; to manufacture cars of any kind, to be propelled on land or water by compressed air.

Newark, N. J.—Empire Tire & Supply Co., under New Jersey laws, with $100,000 capital; to manufacture automobiles, motors, appliances, supplies, tires, etc. Corporators—W. L. Montrose, C. C. Henry, S. J. Campbell, Newark, N. J.

New York City, N. Y.—Carl H. Page & Co., under New York laws, with $5,000 capital; motor parts. Corporators—Carl H. Page, 1627 Broadway; Robert H. Montgomery, 165 Broadway; Henry Bennett Leary, 55 Broadway, New York City, N. Y.

New York City, N. Y.—Renault Freres Selling Branch, Inc., under New York laws, with $100,000 capital. Corporators—Fernand Renault and Charles Richardiere, Billancourt, France; Paul Lavroix, 275 Central Park West, New York City, N. Y.

MERGER PLANS ARE EXPANDING

Many Concerns Would be Involved in the Big Combination—Parts Makers Included.

The projected merger of the Maxwell-Briscoe Motor Co., of Tarrytown, N. Y., and the Buick Motor Company, of Flint, Mich., has in the later negotiations taken the form of a $25,000,000 company, to combine not only these two concerns, but others as well, including parts makers, though the latter are to come in later. The stock to be issued would be $14,000,000 in preferred, and $11,000,000 in common Holders of the Maxwell-Briscoe stock would receive in exchange for each share, two shares of the new preferred and one of the common. The new concern would be known as the International Motor Co., and it is understood that several members of the banking house of J. P. Morgan & Co. stand ready to underwrite $900,000 of the preferred stock, offering it to the public at 97½ with a share of common thrown in, and representing the preferred as a sure 7 per cent. dividend payer and the common as a possible 25 per cent. earner.

In addition to President Durant of the Buick company and President Briscoe of the Maxwell-Briscoe company, the names mentioned in the negotiations include W. P. Hamilton and W. P. Horn, of Morgan & Co., and Otto J. Merkle. The attorneys for the transaction are Ward, Hayden & Satterlee. Both Hamilton and Satterlee are sons-in-law of J. P. Morgan.

Hartford Dealers Decide Show Date.

Because of the great success of last year's effort, the Hartford Automobile Dealers' Association has decided to hold another local show and to give its control over to the men who brought about such excellent results on the previous occasion. The committee chosen to conduct the affair consists of F. W. Dart, S. A. Miner and E. G. Biddle, and the dates chosen are February 27 to March 6. The show will probably be held in Foot Guard Armory, unless the new National Guard armory is completed in time to be available. Last year this committee, after closing the show affairs, paid exhibitors a dividend of 92⅔ per cent.

Creditors Attach a Body Concern.

The Auto Body and Top Manufacturing Co., a Hartford concern recently organized to do a chiefly local business and conducted by Walter a French and Joseph T. Tilden, has suspended business for the time being because the contents of the factory have been attached. The attaching creditors are F. S. Carr & Co., of Boston; the Sewa-d Rubber Co., of Berlin, Conn., and the Bonner-Preston Co. and Harry Goldberg of Hartford, Conn.

FRANKLIN Automobiles

The big surprise of the Glidden tour.

Nobody who knew the Franklin, was surprised at what it did in the latest Glidden tour, but the worshippers of the old-time fetish enormous weight and bulk, with hard riding and encumberance, complicated water-cooling system—found their idol pretty badly smashed. To them the Franklin performance was the surprise of the tour.

Converted Skeptics

This being the first time a Franklin ever entered a Glidden tour it was watched probably closer and sharper than any other automobile in the contest. The skeptics were all ready to say, "I told you so," but instead they threw up their hands and declared, "We never would have believed it."

Perfect Scores

Of the four Franklins entered two made perfect scores. Not one was penalized for anything but broken springs.

These had previously been driven from 8,000 to 10,000 miles. The springs were not wrapped. 90 per cent. of the other automobiles had their springs wrapped or were equipped with shock absorbers. All the Franklins were stock cars, without any special preparation.

Franklin Air-Cooling

In spite of the many hills, hard pulling, and much low gear work, no Franklin ever had to stop for a minute to cool off. Nearly every water-cooled automobile had to stop somewhere to cool off. Some of them at times had to stop every 20 or 30 miles to take on water. Many steaming and boiling radiators were to be seen; some were leaking.

An Unbiased Report

The *Horseless Age* says, "That Air-cooling is a success has been fully proven by the performance of the Franklin cars. They are among the leaders at the night control each night."

"The performance of the Franklin Type D was a revelation. It made better average time, up hill and down, than some of the 50 and 60 h. p. six-cylinder cars. The engine ran perfectly and without the slightest sign of overheating, although it was put to every test of hard pulling and overloading that it seems possible for an engine to be subjected to."

Climbing

Even the Franklin runabout climbed better than automobiles with three times the power rating.

In one case the Franklin towed two bigger cars up a steep hill.

The type G went up some mountains on the second gear which many of the water-coolers had to take on the low gear.

No Mechanical Troubles

Day after day the official observer reported "Nothing done to Franklin cars."

The regular equipment bag, and the extra equipment bag were never opened on any of the Franklin automobiles.

Two Franklins had the 1909 high-tension magneto ignition only, and not even a plug was removed from these engines. There were no ignition troubles whatever.

The Easiest of All Tires

The Franklin had less tire trouble than any other automobile. The only tire trouble with Franklins was cutting, by glass.

The only car in the entire contest that had no tire trouble whatever was a Franklin—a model H six-cylinder automobile carrying five passengers and five suit cases.

This contest has demonstrated convincingly to many who never realized the truth before, that Franklin air-cooling, light weight and easy riding gives more going ability and more comfort and safety than you can get out of a heavy, hard-riding water-cooled machine no matter how it is rated nor how much it costs; and that you get all this with less trouble and lower operating cost.

Owning-cost is what counts—owning-cost for actual road ability. That makes Franklin economy.

Building Inferences on Fact.

The temptation to manufacturers to exploit the really wonderful records made by some of their cars as to up-keep cost is practically irresistible, and it is only an evil temptation to be resisted where there is lacking a degree of caution which will properly limit the claims and reasoning with which such figures are given out. Unfortunately the enthusiasm of the moment quite frequently outbalances good judgment when the public is to be informed as to the performance of the cars, and exaggeration of suggestion is employed to give the impression that any purchaser may reasonably expect to get equally good results and to incur as little expense.

Opposed as are the epigrams that "Figures never lie" and that "You can prove anything by statistics," they both have application in the elaborate returns from inquiries as to upkeep cost. Every manufacturer is at liberty to conduct his own inquiry in his own way and to strangle unfavorable figures if he feels like it. There is an advantage in devising the plan of the inquiry so that it will bear the stamp of completeness and thoroughness, thus being more convincing to the careful student of figures, but deficiencies in this respect can, to a certain extent, be covered over by the force of heavy advertising and clever arrangement of the tables.

Undoubtedly the individual work of several manufacturing concerns in obtaining data as to the upkeep cost of their cars, has been a valuable contribution to the general subject of motoring, and the reward that they have found in examples of durability and economy in their cars has been adequate compensation. In most instances the facts thus obtained have been used with commendable discretion. Their mere presentation as facts, bare of obvious comment or extensive reasoning, is impressive and favorable, but the addition and dressing up which such statistics are only to apt to receive in the way of inferences and reductio ad laudatum, with a wealth of assertions about "average cost" that the buyer may rely on, rather pull on those who dislike being pushed into judgments and conclusions.

The prospect of there ever being any standard or uniform method of inquiry and publication of results as to upkeep cost and durability of various makes of cars is infinitely remote because of the practical difficulties in the way. To the prospective buyer, however, some such scheme would appeal, as giving him absolute and correct comparisons. Lacking such a system, it remains for the makers themselves to prepare and publish such statistics in such a manner that no doubts will arise but that the conclusions expressed in connection with them are fully warranted by the facts.

The Problem of the Agency.

It is generally admitted that the selling of automobiles is constantly becoming a more difficult matter, and that as time goes on, the volume of sales business is growing to depend less upon the merits of the car itself and more upon the sagacity and persistence of the salesman. It is also acknowledged that this is resulting in a weeding out process among selling forces which is destined to have a clarifying influence on the trade in the long run. In general this tendency is remarked in connection with the selection of salesmen. As a matter of fact, however, it is even more marked in the case of the agent. For where the salesman's responsibility is practically ended with the closing of the sale and delivery of a car, the agent is expected to take good and faithful care of all his customers even after they have gone abroad with their machines, in order to round them up at the end of a measurable season, ready for new cars—or so his function may be construed.

In this respect, it is undoubtedly a fact that the manufacturer is called upon year by year to face a problem of growing difficulty in the placing of his agency contracts. With the closing in of the lines of business and the increasing rivalry of the trade, it is no longer possible to retain an agent for his business ability alone, for his experience in the industry, nor for the patronage which his position or acquaintance may be supposed to command. The ideal agent must have each of these qualifications, and must in addition, be an alert, clear-headed business getter, as well as a more or less successful executive.

The time has passed when mere geographical location and social pull were sufficient qualifications to suit the careful sales manager. Men who are really competent agency heads, are being sent about from coast to coast, and from north to south and south to north, to replace other men whose success has been tempered with varying degrees of dissatisfaction. There are good heads of departments or branches, who understand the selling business, and who possess sufficient adaptability to enable them to comprehend the varying conditions imposed by changes of location. It is a noteworthy fact in this connection, that just such changes are not being made indiscriminately, but are governed by the requirements of the posts and by the fitness of the men to fill them.

Hitherto, much of the really hard work that has been done in the industry has been carried out in the manufacturing departments. Slow and expensive manufacturing processes, constant alterations of design, unsatisfactory manufacturing processes, constant alterations of design, unsatisfactory and ever changing market conditions, have combined to render the path of the factory man a thorny one. Now, with the increase in specialization, the growing use of special tools, and the tendency to build cars on the multiple production basis wherever practicable, it would seem that a reversal

Digitized by Google

is about to take place—that the factory man must be due for a period of more orderly career than has been his lot hitherto, and that the man in the field must live the uneasy life. All of which must tend to complicate the selection of agents, and deprive that section of the industry of the sympathy which it actually merits.

Ethics of the Repair Shop.

There are so many unsatisfactory features connected with the business of repairing cars, and the difficulties attendant upon any attempt to run it along strictly business lines are so nearly insurmountable, or so it appears, that the dealer who is not absolutely dependent upon it as an adjunct to his garage interests, is sometimes tempted to discontinue it entirely, and frequently fails to give it the attention which it really merits. As a source of revenue, the profitable nature of the automobile repair shop is beyond question. Yet in times of prosperity in the selling line, or in the operation of the garage alone, the real value of the repair shop as an adjunct to the other departments, may not be fully appreciated.

The repairman who is also an agent, ought to be at considerable pains to hold the patronage of owners of his particular make of machine, not simply for the sake of his own convenience in the matter of selling replacements and handling repairs to mechanism with which his mechanics are thoroughly familiar, but also for the sake of retaining the ear of the owner. By this means, the owner, and through him the manufacturer, of whose forces the agent is practically an enlisted member, are enabled to keep in closer touch than is possible where the car goes out of existence, as it were, when it leaves the floor of the agency. The result of this is that if the repair work is handled with sufficient tact, the shortcomings of any given model may be bridged over in many instances, mistakes in design and construction may be rectified without undue hardship on either side, and the rival agent is deprived of the coveted opportunity of drawing invidious comparisons.

In this connection, the possibility that unscrupulous repairmen who are interested in cars of other makes may even countenance the deliberate inflation of repair bills, or wink at the tricks of disgruntled mechanics who seek to satisfy some grude against the manufacturer, is one which is so real as to assume almost the appearance of a risk in this connection. No matter how abundant the owner's faith in his machine, it cannot be proof against continued and apparently well founded insinuations of its inferiority. Nor is it likely that even unmerited criticisms will fall upon wholly deaf ears, if he happens to have a grievance of some sort against the agent from whom he purchased the car.

It is thus a very good thing from the dealer's standpoint to retain the good will of all his customers. When in order to do this, it becomes necessary to create an efficient and wholly practical repair department, no pains should be spared to do so, even though the direct monetary reward be not a large one.

As to reaching out for business on cars of other makes, much depends upon the matter of shop equipment, and the readiness with which duplicate parts may be obtained. Where replacements are not easily available, the well equipped mechanic is always ready to turn out a substitute—more or less suitable for the purpose, according to his own intelligence and the facilities at hand. But in nearly all cases, the cost of such replacements will be higher than those demanded by an honest maker; and where such is the case, the interests of the customer are not served to the best advantage in consequence.

Whatever may be the evil effects upon the selling business which result from the "knocks" of envious or malicious rivals, the effects of the customer's own dissatisfaction on questions of repairs are worse, since they effect the proprietor directly and are in no way lightened upon the broad back of the manufacturer. To the man who accepts it as a requirement of the agency the repair business thus becomes a necessary evil, and to him who makes it a specialty, a source of deep difficulty. At the same time, it is not without its compensations, and when operated under favorable conditions, these are of overwhelming importance.

The Army Chauffeur.

An interesting reflection on the chauffeur problem as governing the reliability of car performance is furnished by the remarkable incident in connection with the use of the army automobiles at the recent manoeuvres at Pine Camp. Two cars were supplied for the purpose, of the same make and model, and supposedly duplicates in every respect. At first both machines were unsatisfactory, and seldom were in a condition for service. Then a guard was placed over one of them, and this machine was not available for use save by order of the commanding general. At once the conditions of unreadiness disappeared, with the result that the machine created an impression which is aptly conveyed in General Grant's expression, "The automobile is a necessary adjunct to the army's equipment." The other automobile, a mate to the one which excited General Grant's remark, received an adverse report from the officers to whose use it was assigned. This machine was not guarded and positive evidence is supplied that its use was not confined solely to military service.

The conclusion therefore is justified that the civilian chauffeur, not the manufacturer, may be blamed for the unsatisfactory action of the one machine. And, that the automobile as an instrument of transportation is not available for use in time and place of battle is a conclusion which is not borne out by facts and therefore is unjust and unfair. It will be interesting to read the report of the use of power driven vehicles in the army when the machines are exclusively operated by men of the engineer corps who are subject to army discipline.

COMING EVENTS

Sept. 1, 2, 3, and 4, Chicago, Ill.—Chicago Motor Club's postponed 1,000-mile reliability run.

Sept. 7, Columbus, Ohio.—Columbus Automobile Club's race meet.

September 7, Lowell, Mass.—Lowell Automobile Club's 200 miles road race, on Merrimac Valley boulevard.

September 7, Columbus, Ohio—Columbus Motor Club's 24 hours endurance race at Columbus driving park track.

September 7-12, Hartford, Conn.—Connecticut State Fair Association's outdoor show and grand circuit races at Charter Oak Park.

September 12, Louisville, Ky.—Louisville Automobile Club's race meet at Churchill Downs.

November 26, Savannah, Ga.—Automobile Club of America's (New York), 400 miles outlaw race for foreign cars.

December 31-January 7, New York City—American Motor Car Manufacturers' Association's annual show in Grand Central Palace.

January 16-23, New York City—Association of Licensed Automobile Manufacturers' annual show in Madison Square Garden.

SMALL FIELDS AT WILDWOOD MEET

Postponed Races Attract 10,000 Spectators —Dennison, Bourque and Wilkie Capture Nearly All the Honors.

A small field of competitors which gave practically no opposition to one or two cars, made the postponed boulevard meet at Wildwood, N. J., on Monday last, 3d inst., not as interesting as otherwise might have been the case. The meet had been postponed from Saturday because of rain, but despite the lay over more than 10,000 season resorters and week-enders witnessed the events, all but one being at one mile.

Two accidents before the meet fortunately did not prove serious. The accident in which Richard Sellers, a well-known Philadelphia club man, was injured, was unusual. Sellers was riding in Richard Williams' Pennsylvania racer, when the top of the coil box flew off and jammed in the clutch operating mechanism, so that it could not be released. The car was running at better than a mile a minute when the mishap occurred and two alternatives presented themselves to Williams as he neared the end of the course. One was to run into the inlet, and the other to turn into a cross road. The driver took the latter choice and the car overturned, rolling over and then righting itself. Sellers fared worse than Williams, who escaped with severe contusions and lacerations of the arms and body. Sellers' shoulder was dislocated besides other injuries.

The other accident occurred to Walter Vennel. The hood of his Stanley steamer worked loose and flew off, striking Vennel in the head and shoulders. He was badly cut but not seriously.

Differing from Saturday, when it rained in torrents, the course was thoroughly dried and smooth. Good time resulted, but the records for the course, established on July 4th, were not touched. A. A. Dennison, William Bourque and Edward Wilkie had easy picking, winning every event to which they were eligible. The summaries:

Gasolene cars under $1,250—Won by Edward Wilkie (Buick); second, E. W. Smith (Middleby). Time, 1:19.

Gasolene cars, $1,251 to $2,000—Won by Edward Wilkie (Buick); second, E. W. Smith (Middleby). Time, 1:22.

Free-for-all—First heat won by William Bourque (Knox); second, Walter Vennel (Stanley); third, J. W. Parkin, Sr. (Parkin). Time, 0:49⅘. Second heat won by A. H. Dennison (Knox); second, D. Walter Harper (Stanley); third, W. H. Sharp (Sharp Arrow). Time, 0:50. Final heat won by Dennison; second, Bourque. Time, 0:50.

Gasolene cars, $2,001 to $3,000—Won by W. Bourque (Knox); second, W. H. Sharp, (Sharp-Arrow). Time, 0:54⅗.

Gasolene cars, $3,001 to $4,000—Won by William Bourque (Knox); second, J. W. Parkin, Jr. (Parkin). Time, 0:50⅘.

Four cylinder gasolene cars over $4,000—Won by William Bourque (Knox); second, H. J. McMichel (Stearns). Time, 0:54⅗.

One kilometer time trials—Won by A. H. Dennison (Knox); second, Wm. Bourque, (Knox); third, J. W. Parkin, Jr. (Parkin); fourth, D. W. Harper (Stanley); fifth, Ed. Wilkie (Buick). Times, 0:28, 0:29⅕, 0:30, 0:31⅗, 0:41.

Steam cars only—Won by D. Walter Harper (Stanley); second, Walter Vennel (Stanley). Time not taken.

Mile time trials—Won by A. H. Dennison (Knox); second, William Bourque (Knox); third, W. Parkin, Jr. (Parkin); fourth, W. H. Sharp (Sharp-Arrow); fifth, Ed. Wilkie (Buick). Times, 0:47⅗, 0:48⅘, 0:50⅗, 0:53, 1:08.

Pickens Again Hankers for $port.

Once more William H. Pickens emerges into the limelight of publicity. Pickens, who was the United $tates Motor Racing Association, but now "of the Federation of American Aero Clubs, with headquarters in Chicago," as one of the Chicago papers puts it, is manifesting again his interest in automobile racing as $port. The coming State Fair to be held in Mississippi looks good to him as an opening and he has written to the management proposing a series of automobile races by expert drivers as a feature. Pickens has looked over the ground at Jackson, says the track there is one of the best in the country for such races, and has presented a brilliant publicity program Jackson does not appear to warm to the Pickens program, however. Possibly his fame has preceded him thither.

Asbury Park Turns Latham Down.

Clouds have fallen over the pathway to success that C. Wood Latham blazed for himself when the city of Asbury Park engaged him to organize its September Automobile Carnival. They have taken the shape of allegations concerning unpaid bills for board and entertainment. Whether they are nothing more than allegations, or not, they have shed a cold shower upon his budding hopes, for the business men promoting the affair have given formal notice that no longer is he authorized to represent them in any way.

Australian Hospitality for American Tars.

Arrangements are being made by the Automobile Club of Victoria, Melbourne, Australia, to entertain the officers of the United States Navy when the fleet visits Australia in September. The entertainment will consist of an automobile trip to Fernshaw and the Blacks' Spur.

The secretary of the A. C. V. has sent a circular to the club members requesting them to supply the cars and act as hosts to the sailor occupants of their respective machines.

TO PROMOTE METROPOLITAN RACES

New Association Organizes with That Aim —Promises to Steer Clear of Friction with Other Bodies.

To undertake the direct local control of automobile racing around New York City, a new organization has been formed, which is to be known as the Metropolitan Motor Association. It is not wholly new, however, being more or less in the nature of a phoenix emerging from an egg warmed in the ashes of "Tom" Moore's so-called Metropolitan Automobile Association and later Automobile Manufacturers' Committee. It starts out with the apparent conviction that there is a field open to its occupancy where it can exercise its propensity for promoting sport without engendering friction with other organizations.

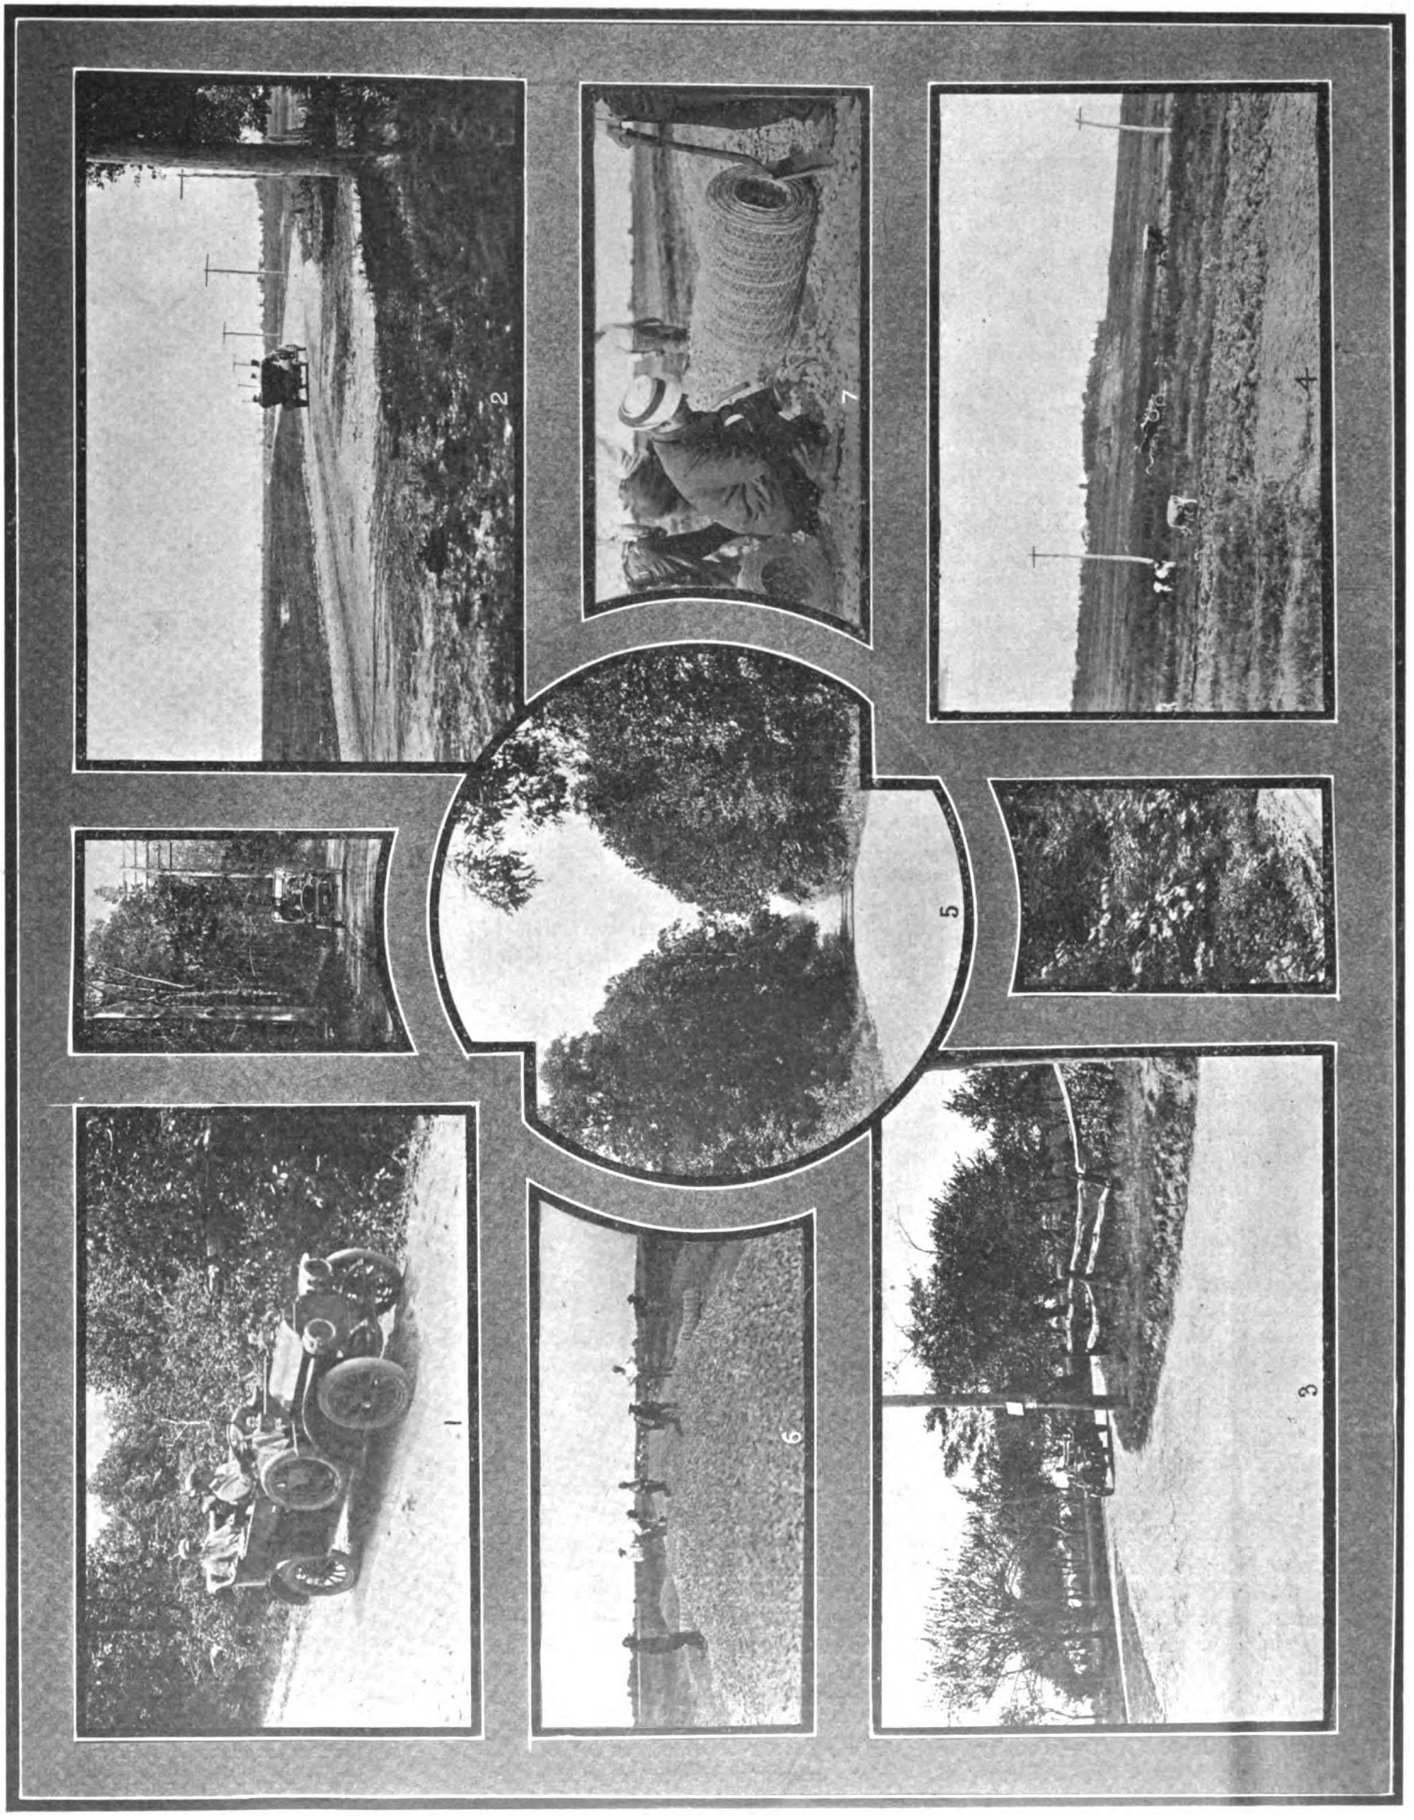
Following a convivial dinner at Rector's, a meeting was held last Friday at which a permanent organization was adopted, and the "objects" of the organization set down in cold black and white. Furthermore it was decided to hold a 24 hour race at Brighton Beach, together with a number of sprint races.

The "objects," as formally indited, are:

"To support only such contests held in and within 75 miles of New York City as have for their first object the stimulation and growth of public interest in automobile events and which will benefit the sport and industry as a whole.

"To eliminate from such contests inexperienced drivers and officials.

"To regulate the number, length and conditions of contests and races.



"To safeguard the interests and safety of all contestants and the public by rigid supervision of courses over which contests and races are to be held."

The association is careful to disclaim any intention of trying to usurp powers or functions of the American Automobile Association, and hopes to find a basis "whereby all interests, including clubs, associations and contestants can get together, without friction."

Those present and who have been enrolled as the charter members, were: H. A. Lozier, Lozier Motor Co.; C. A. Singer, Palmer & Singer; Paul LaCroix, Renault Co.; E. R. Hollander, Fiat Import Co.; C. F. Wyckoff, of Wyckoff, Church & Partridge; C. M. Hamilton, Isotta Import Co.; Harry Houpt, of the Harry Houpt Co., and F. E. Moskovics, of the Allen-Kingston Co. The officers chosen were: C. F. Wyckoff, president; E. R. Hollander, vice-president; Harry Houpt, treasurer, and Walter Allen, secretary. To help in the arrangements for the Brighton Beach races, the services of Fred Wagner have been enlisted, and for the 24 hour event at least two entries from each of the members is promised.

VANDERBILT COURSE COMPLETE

Perfecting Arrangements for the Great Race —Mammoth Grandstand Projected— Troops to Maintain Order.

With the announcement of the complete course of the Vanderbilt cup race there is supplied practically all of the advance information that can be desired, except the final list of entries. The race itself, as previously announced, is to take place on October 24, and the course selected is in Nassau county, Long Island. The distance will be 254 miles or ten laps around a circuit of 25.4 miles. Of the course to be used, 11 miles are on the new Motor Parkway and 14.4 miles on the public roads. There is but one railroad crossing at grade and but eight turns of any consequence are encountered. A grandstand to seat 10,000 people will be erected and 11 miles of parking space along the Motor Parkway will be set aside for those who wish to view the race from their cars. Bonds for $25,000 are to be given that all damages to the roads will be repaired, and 1,200 uniformed troops will guard the course.

The nature of the course chosen is such as to give opportunity for tremendous and sustained speed. As indicated in last week's Motor World, the 11 mile section of the Parkway which is to be used is being hastened to completion and its turns are being banked with a care and skill that will rob them of practically all danger. Tests of the curves are to be made in a few days with a racing machine, to make certain that the degrees of pitch and curvature have been laid out in such a way as to take care of the enormous centrifugal force developed in fast work. If the tests disclose the possibility of improvements, the necessary changes will be made, so that by the time the race occurs the Parkway section will be in perfect shape.

Similarly a great deal of preparation and care will be given to the open roads that are to be used, the curves being banked where it is possible and widened where conditions permit. All the bad holes and bumps will be given attention and the whole surface given treatment to prevent dust.

It was not until last Saturday night that the final details of the course were given out. The accompanying map shows the route the machines will traverse and the location of the grand stand, together with the chief points marking the path.

The northern boundary of the course is the well known Jericho turnpike, beginning at the old Westbury road about three miles east of Krugs Corner and running 10 miles east to the intersection of the Woodbury and Hicksville macadam road.

The western boundary of the course is composed of a portion of the old Westbury road running south from the Jericho turnpike to the Old Country road and along the Old Country road about an eigth of a mile to Whaleneck avenue, thence south to the beginning of the Motor Parkway.

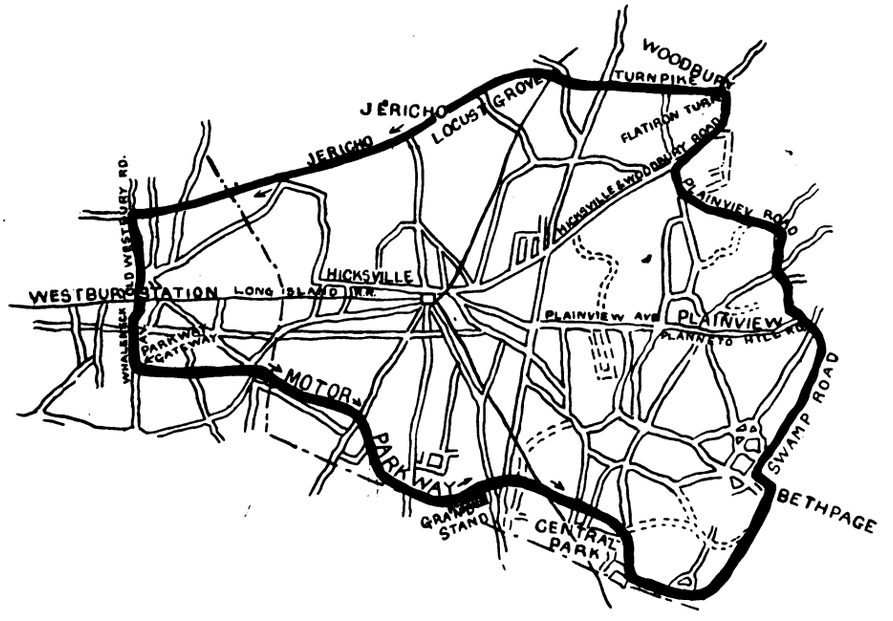
The southern boundary is composed entirely of the new cement Parkway beginning at Whaleneck avenue and paralleling an abandoned branch of the Long Island Railroad known as the Hempstead branch, for a distance of nearly 11 miles to a small settlement called Bethpage.

The eastern boundary of the course begins at the termination of the cement Parkway at Bethpage and runs north along Round Swamp road to its intersection with the Woodbury and Hicksville macadam road, along which it continues to the Jericho turnpike, where there is a sharp left turn known as the "Flatiron." From this turn the course practically coasts westward on Jericho turnpike and thence south to the beginning of the Parkway.

There are eight sharp turns on the State and county road portions of the course, but the Parkway turns are all beautifully rounded and banked. The surface of the cement is as smooth as a city concreted street and the possibilities for high speed are quite enough to satisfy the ambition of the most daring racing drivers in the world.

It is proposed by the Motor Parkway corporation to erect a mammoth steel grand stand on the south side of the cement roadway about four miles from its beginning. From this stand spectators will have a bird's-eye view to the east and west for the entire 11 miles so that it will be possible to see the cars as they attain their highest speed on the beautiful S turns and as they pass over the graded viaducts crossing the railroad and intersecting public highways. In extent this grandstand view will be about ten miles greater than at any previous Vanderbilt race.

COMPLETED SECTION OF LONG ISLAND MOTOR PARKWAY, SHOWING S CURVE IN DISTANCE.



The new course might aptly be termed "The Plateau Racing Drome." The first impression of the visitor is that he would like to be up in a balloon a few hundred feet and see the entire circuit, and this would be quite possible because of the almost monotonous flatness of that section of Long Island. Beginning at the Jericho turnpike and the old Westbury road the course sweeps through the famous Hempstead plain country, where there is not a vestige of shrubbery or any wood. All of the cementway passes through a country of the same character—nothing in sight save the low meadow grass and an occasional cow grazing.

After the course leaves the cementway

Digitized by Google

and comes back to the public highway at Bethpage, there is what has been termed in the past, Manneto Hill, but it is such a slight affair it is hardly worthy the name. The foliage along Round Swamp and Plainview roads is quite thick, and if there is any dangerous part of the course it would be in this section, where the turns are quite frequent and where the view ahead is generally of short range. For the most part the racing cars will be tearing through either a beating sun or rain, as the day may happen to afford. The only shade is along Jericho turnpike where the trees are quite tall and in parts extremely beautiful, sometimes overlapping the roadway.

in the time allotted. All of the crushed stone and the cement that is to be used on the job is on the ground, together with the steel netting which forms the foundation for the cement roadbed. The wire fencing has been contracted for and is almost ready for delivery. This fencing will be about five feet high and composed of ten parallel wires set close together and held in position by vertical wires about a foot apart. Work on the steel span at Central Park and the cement bridges in the section is being pushed rapidly, and three toll lodges will be completed in time for the race. Because of the military guard and the fact that all four sides of the course are much

MAP OF THE VANDERBILT CUP COURSE

Permission to use the public roads was obtained from the board of supervisors of Nassau county at a hearing at Mineola, L. I., on August 3d, when A. R. Pardington, of the Vanderbilt Cup Commission, appeared and gave a statement as to the measures that had been taken both to protect the interests of the county and to safeguard the public. Several prominent residents of the county appeared to recommend that the board grant the necessary permission and no opposition was presented except by one resident of Westbury, whose objections proved unavailing. Accordingly the counsel for the board was instructed to draw up the regulations and bonds by which the county will be held exempt from damages and to assure a satisfactory recompense for such repair expense as the race may cause in connection with the roads.

The entries for the race close September 1, and already a number have been received. The elimination race for the American cars will be held on October 10, and Pardington promises that the Parkway section will all be completed by that time. There are a number of contractors on the work and their sections are so short that it will be an easy matter for them to finish more isolated than in previous races, it is thought that there will be no trouble in controlling the spectators.

American Thomas Car Reaches Paris.

Escorted by a great parade of automobiles the American Thomas car, carrying George Shuster, George Miller, Captain Hans Hanson, and George McAdam, arrived at the office of Le Matin in Paris at 8 p. m., on Thursday, 30th ult., the second of the New York to Paris "racers" to reach the French capital, but, by virtue of its allowance of 30 days against the German Protos car, the winner of the contest. The Protos, as already announced in the Motor World, arrived in Paris on July 26th.

The escort for the Americans drove out 25 miles to Meaux to meet them, and the entry into Paris was a triumphal progress, the gay crowds along the brilliantly lighted boulevards shouting "Vive le car Americain!" There was just one incident that jarred, but it resolved itself into an amusing feature of the parade. When the American car with its dust covered khaki clad crew reached the Place de l'Opera and was in front of the Cafe de la Paix, it was stopped by a gendarme.

"You are under arrest," he declared. "You have no lights on your car."

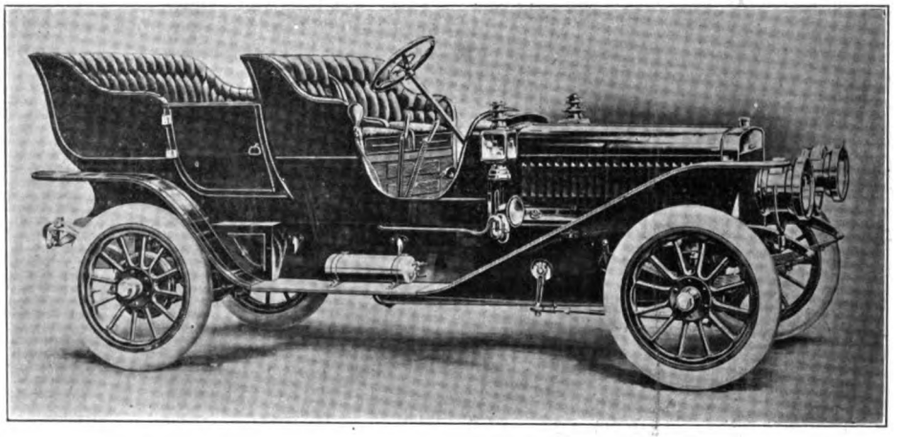
A crowd of Americans rushed from the cafe and explained the situation to the officer, telling him that the machine was finishing the New York to Paris race, while Shuster declared that the lamps had been broken on the journey, but no explanation moved him. A man on a bicycle came forward and offered his lantern to the crew, but it could not be detached from the machine. Finally the bicycle was lifted bodily onto the front seat of the automobile and placed between Shuster and Miller while the owner climbed into the rear seat and the car was allowed to proceed.

Formal award of the prizes will be made toward the end of the current week, it is expected. The committee on the contest are to hold a meeting for that purpose and no doubt is entertained that they will award first honors to the Thomas car. The Berliner Zeitung am Mittag, however, has filed a protest against the award of anything but the first prize to Lieut. Koeppen of the German Protos car. That paper, which holds that the handicap placed on the Protos was unsportsmanlike, declares that the Imperial German Automobile Club fully shares its view of the situation, and will probably address formal representations to the committee in its own name. The Zeitung also requests the German press to take up the question and join in the protest because the "matter has a certain national importance."

City Wants Two More Automobiles.

New York City again is in the market for two automobiles. The cars are for use in the department of docks and ferries, and the sealed bids were opened on Tuesday last, 4th inst. This is the second time that this department has advertised for cars this year. On the last occasion, in April, the bids were thrown out as the lowest offer was $7,500 for the two machines. The present competition resulted in a bid of $6,490. The contract has not yet been awarded.

The specifications call for two new 4 cylinder water-cooled cars. The interesting features of the specifications are found in the elimination of the phrase, "American make," and that the body may be of "steel casting" construction. While chrome steel is called for in the axles and crank shaft, and its composition is specified, the clause which formerly read "each bidder shall submit with his bid a guaranteed manufacturer's analysis and test of the steel used for the above named purpose," has been altered so that now it stands, "the successful bidder shall submit with his bill a guaranteed," etc. The cars need not be of the 1908 model.



The bids received were from Cordner & Flinn, who offered two Acmes for $6,490; The American Locomotive Co. with Berliets at $7,000, and Homan & Schulz with Nationals at $7,400.

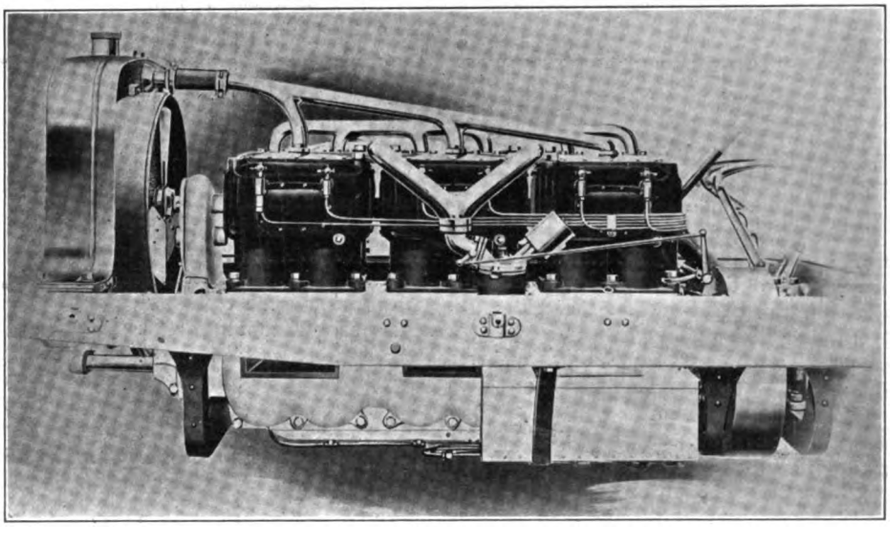
SIX-TEEN-SIX AND ITS SISTER

New Winton Model to be of Increased Power—Only Minor Changes to Appear in Its Predecessor.

Following the all-six-cylinder policy adopted last year, the Winton Motor Carriage Co., Cleveland, Ohio, has decided upon an extension of its line. Two distinct models are to be manufactured hereafter, both to be known as the Winton Six. One, which will be practically a continuation of the Six-Teen-Six model, will be rated at 48 horsepower, and will be equipped with a five-passenger body. The other will be of 60 horsepower output, and will carry a seven-passenger body. Deliveries on both models will begin shortly.



WINTON SIX-CYLINDER, 48 H. P.

In general design no changes have been made. The cylinders are offset, and cast in pairs. The valves are of the two-piece variety and are mounted on the right side of the motor. The valve tappets, springs, and plungers are enclosed in housings covered with detachable pressed steel plates. No moving part of the motor is exposed except the fly wheel. The starting device is continued without change. Compressed air, stored in a tank from the front cylinder, is admitted to each of the cylinders in rotation through a rotary distributing valve, which is the only moving part of the system. The air, admitted during the firing stroke, exerts sufficient pressure to drive the pistons down past the point of ignition and assists the crank shaft until the regular impulses are established. In order to throw the device into action it is necessary merely to press a button mounted on the dash.

The carburetter has two nozzles and two throttles, interconnected in such a way as to open progressively, the smaller opening first, and later picking up the other automatically. The float is arranged concentric with the aspirating nozzle, and the mixture is compensated automatically without the use of moving parts. Double ignition is employed, the regular system being the Eisemann high tension magneto with distributor, single non-vibrating coil and plugs located horizontally over the intake valves. Accumulators also are provided for use in starting the motor and as a standby.

Lubrication is carried out in much the same manner as on the Six-Teen-Six model, but in simplified form, in that one pump now serves in place of twelve. The crank shaft main bearings, and the two-to-one gears are fed directly by a pump operated by an eccentric on the rear end of the crank shaft. A second pump, operated by the same eccentric, draws the oil drainage from the crank case and returns it to the tank, whence it again passes through the system after being properly filtered. The water circulation is secured by means of a gear driven centrifugal pump, the radiator being of the vertical tube pattern hitherto employed.

MOTOR OF WINTON 48 H. P. SIX-CYLINDER CAR

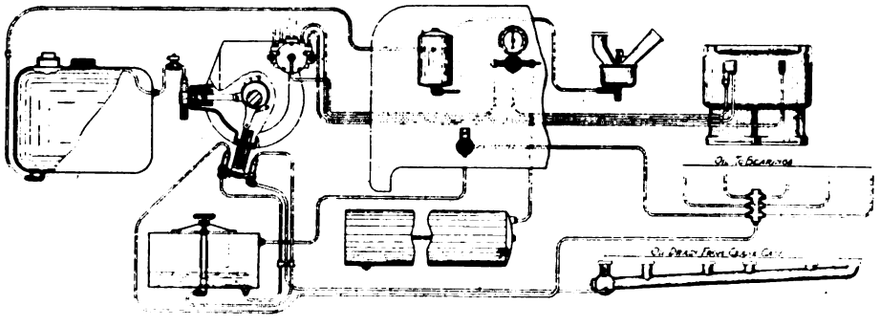
The transmission system differs in the two models in that that used in the 48 horsepower car affords three changes of speed in the forward direction, while the larger car has a four-speed gearset. The master clutch is of the multiple disc type, and has 67 relatively small steel units, 33 of which are mounted on the transmission shaft, and 34 coupled to the transmission spiders, which are connected to the fly wheel. The object of this is to place the group having the least inertia on the part affording the greatest variations in velocity. Six springs, equally spaced about the device serve to effect an even distribution of tension on the plates. As is customarily the case, the clutch pedal and brake lever are interconnected, but the clutch is so arranged that it cannot be locked out of engagement.

The change gear group is of the selective type, mounted on annular ball bearings and affords the usual direct through drive on the third speed, through an external and internal gear combination. By means of a safety mechanism, it is made possible to slip into neutral position without disengaging the clutch, but impossible to enter either of the gears again until the clutch is released.

The propeller shaft is coupled by means of roller type cardan joints, the flexible connection between the motor and change gear consisting of a split bushing which engages the squared end of the main transmission shaft and a similar squared end on the fly wheel. The entire mechanism is completely housed.

The rear axle is of the full floating type, mounted on Timken roller bearings the load-carrying axle tube being of heavy drawn steel tubing. The differential or balance gear is of the spur pattern. Four brakes are mounted on the driving wheel hubs, and are operated through equalizers. They are of the external-internal pattern, and have large areas. No brake attachment is carried on the transmission proper.

The frame side rails and drop sections which carry the sub-frame are of one-piece channel section steel, with heavy gusset plates, and the power plant is entirely supported by the sub frame. Suspension is, as



Digitized by Google

hitherto, by means of the Winton twin ersspring equipment, to which shock absorbers have now been added as a part of the regular equipment. The torsion and radius rod groups are as in the equipment of the present model.

The wheels are: for the 48 horsepower model, 34 inches in diameter, with 12 spokes; for the 60 horsepower car, 36 inches in diameter. All wheels run on Timken roller bearings, this applying to both models and the regular tire equipment specifies the 4½ inch size, quick detachable type.

The main gasolene tank is suspended from the rear of the chassis and is of 22 gallon capacity. Three gallons are contained in a reserve compartment isolated from the main body of fuel. The feed is by pressure to an auxiliary tank, mounted on the dash board, from which it is led by gravity to the carburetter.

All bodies are of wood, constructed after special constructional designs. Mahogany

WINTON SELF-STARTER AND OIL PIPING

dashes are employed, with steel hoods. The bonnets are of aluminum. A steel dust pan extends from the forward end of the motor to the rear of the transmission, making, with the apron, which extends from the radiator to the motor, a complete enclosure for the under side of the car.

Multiplicity of piping and other connections being a common fault in many cars, it is interesting to observe the relative simplicity of the equipment employed on the machines in question. As shown by the accompanying illustration, the air tank for supplying the self-starter is located immediately at the right of the oil tank, with a line leading to the push button and gauge on the dash. The small tank shown on the dash, is the auxiliary gasolene reservoir. The carburetter is shown at the right of the dash. From the first cylinder, two pipes lead, one for receiving pressure to be stored in the air tank; the other pipe is similar to that which leads to each of the six cylinders to distribute air to the cylinders from the supply tank through the distributor valve. Oil leads to bearings and oil drain from crank case are shown at the lower right hand side. The starting crank, which is useful only for emergency purposes and repair service in overhauling the motor, is carried in the tool box. The foot button on the dash takes its place under ordinary circumstances.

POINTS ON SELECTING LUBICANTS

Some Fallacies Concerning Oils That Mislead the Average User—An Expert Offers Suggestions.

Few motorists realize the importance of proper lubrication and the havoc which is wrought by using an inferior lubricant. Many buyers are influenced by the matter of price, without considering quality, or are guided by the advice of a man who is interested in selling the goods on which he makes the greatest profit, says H. E. Haws, manufacturer of Panhard oil. He continues:

Unfortunately much oil is sold in barrel or half-barrel lots, and the dealer's word is practically the only assurance the consumer has that he gets what he pays for. Most of the leading brands of cylinder oils retail at approximately the same price, but of late there has been a flood of cheaper oils, and the car owner is the one that gets the worst of it.

Much has been written recently as to substitution and the tests which a satisfactory cylinder oil should stand. Some of this has entirely missed the point. The tests for the flash point, gravity and viscosity, while interesting to the practical chemist, are unnecessary as far as the motorist himself is concerned. The manufacturer of the several standard grades on the market would be glad to furnish these tests on application.

The determination of the amount of free tarry matter in the oil is the real factor which governs the amount of carbonization to be expected. The catch phrase, "Color Test for Carbon," has even been adopted by some manufacturers, meaning that lightness of color indicates freedom from carbon.

This plausible argument, convincing to the unskilled user, has arisen from the misinterpretation of the word "light" as applied to oils. While it is true that lightness of gravity is of the greatest importance, it is also undeniably true that lightness of gravity and lightness of color are not necessarily correlative.

An almost white oil may be of a much heavier gravity and contain more free carbon than another oil many shades darker in color. Excessive filtration, while removing the color, may, if carried to excess, remove the lubricating properties of the oil, while bleaching with acid, though having no effect on the lubricating qualities of the oil, may leave an acid residue, injurious to cylinders and pistons.

The consumer should therefore be guided by the reputation of the manufacturer, and not be influenced by a few cents a gallon saved, which may mean many dollars spent later for repairs.

It often occurs that a car owner will condemn a certain brand of oil which another motorist finds entirely satisfactory. This is because different motors require different grades of oil.

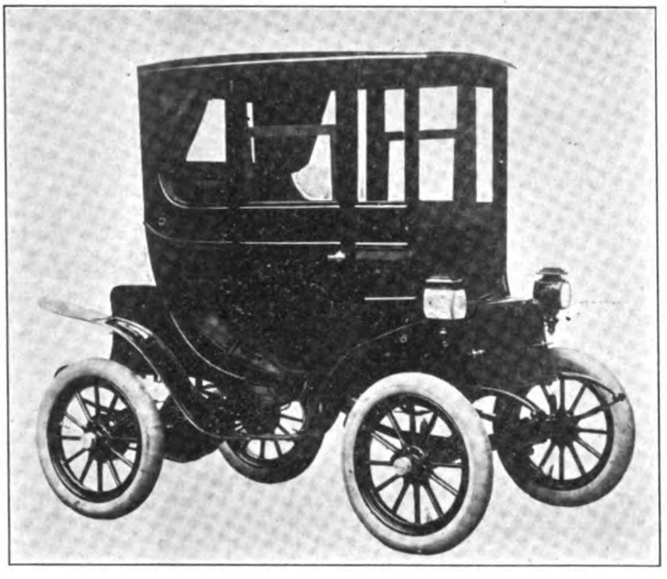
Weakness of the Expanding Clutch.

While in many respects the positively actuated internal expanding clutch is superior to either the leather faced cone or the multiple disc types, its chief point of weakness is in the number of small parts involved in its makeup. It is necessary that these shall be properly adjusted to one another, and kept amply lubricated at all times, regardless of the fact that the centrifugal force generated tends to throw out any liquid lubricant which may be applied to it. While many devices of this type are highly successful, the fact that they require greater care in order to produce equally good results with those of the other two types, is more or less of a drawback to their use. It is necessary with a device of this sort, to see that the moving parts are properly adjusted at all times and the adjustments secured against lost motion and working back. From the standpoint of the designer, this type presents far more serious difficulties than any other, since it is more complicated, though not necessarily composed of a greater number of parts.

Evil of Over Long Split Pins.

There is a deplorable tendency among manufacturers to use split pins which are of much greater length than is absolutely necessary for the work to which they are assigned. It is only required that the open end of the pin shall protrude from the part to be locked just a sufficient distance for the ends to be slightly parted. When the ends are long enough to be literally wrapped around the part, the tendency is for them to be weakened from repeated flexure and to break short off, leaving the pin free to work back through its hole. Besides, the extended ends are a menace to the flesh.

Binding Screws that Need Watching.



Magnetos which are designed to be readily detached must be watched to see that the binding screws do not become loose. Should this occur there is great danger of the gears becoming sufficiently out of mesh to permit of their climbing, which in a very short time will result in stripping the teeth.

FOUR PASSENGER ELECTRIC COUPE

Waverly Branch of Pope Motor Car Co. Brings Out New Model—Its Convertibility a Feature.

In the convenience of the electric vehicle is found ample reason for its extensive use in and about cities. Realizing this, the makers of these machines are continually striving to produce new models which are useful and comfortable above all else. Particularly well suited to the purposes of the town car are the closed vehicles, an instance typical of this being found in the case of the new four-passenger coupe, which the Waverly branch of the Pope Motor Car Co. has just produced.

POPE-WAVERLY FOUR-PASSENGER COUPE

VIEW SHOWING SEATING ARRANGEMENT

This vehicle has the outward aspect of the familiar light, two-passenger coupe, except that the fore part of the body is designed more after the fashion of the extension brougham. By this means, space is secured for an extra seat affording room for two additional passengers, who sit facing the driver. The interior is, in fact, practically the same as that of a horse-drawn brougham, except for the steering lever and controlling devices, and is equally as roomy. For runabout, theatre and shopping as well as general runabout service, it is the equivalent of an electric cab minus the driver. As it is scarcely more cumbersome than the two-passenger coupe, it serves as well for two or four-passenger service. Being essentially a sociable affair also, it is admirably adapted to what is known in carriage parlance as "general family service."

A pleasing variety is made possible by the fact that the top is demountable. When removed, the effect of an open victoria is secured, which, for warm weather uses, may be enclosed by a full leather top if desired. In either case, there is nothing suggestive of a concerted body, either in ungainliness or awkward protruding fittings. The accompanying illustrations show its appearance with the full wood top, both externally and internally.

Its specifications include single motor, of special design and double overload capacity; "herring bone" gearing and 30-cell, 11-plate battery, of 10 and 20 cell groups, arranged in the front and rear compartments. There are two foot and one electric brakes, side steering lever, and a combined voltmeter and ammeter, for indicating the condition of the charge. The body sill is dropped in the center, giving a lower center of gravity and easier entrance than the straight sill type, the length being 89 inches, and the inside seat width 44 inches. The wheel base is 68 inches, and the tread 54 inches.

Double Drive for Extra Speedometer.

To save the nuisance of having to peer over the shoulders of the driver in order to catch a glimpse of the speedometer which is mounted on the dashboard, it is convenient to have a second instrument mounted in the tonneau. For this purpose at least one maker is marketing a special form of double drive whereby the installation can be made readily. It is possible to employ the principle without using this device, however, by using two independent instruments, one driven from either of the front wheels. In this case, the readings of the two will be found to form an interesting check upon one another.

Why the Lamp Sometimes Smokes.

Motorists frequently experience no little difficulty from the smoking of oil lamps when first lighted—regardless of care taken not to have the wick too high when igniting it. The difficulty arises through a variation in the rates of feed when the lamp is hot and cold. As the burner gradually becomes heated, the oil volatilizes more rapidly than before, possibly becoming somewhat thinner as well, so that a larger flame is developed, even without altering the position of the wick. If the height of the wick is readjusted some minutes after lighting, and before the car is started, there should be no trouble from this source. Care in this respect is important, because a smoky lamp practically eclipses itself.

Wiring Diagram on the Car.

Every car owner should be sufficiently familiar with the construction of his machine to be able to reach any part in an emergency with the least possible loss of time and labor. Frequently there are several long ways and only one short way of getting at an enclosed part. The owner should know how to go about his repairs in the most systematic and time saving manner. As a ready reference in time of need and a handy reminder when overhauling the mechanism, it has been recommended frequently that a wiring diagram be carried permanently mounted on some part of the machine. This is well enough as far as it goes, but it should be supplemented by a diagram of the layout of all oil and fuel piping.

Necessity for Tight Pipe Connections.

It is absolutely necessary that the pipe connections between the bottom of the radiator and the pump be kept perfectly tight. Otherwise whatever leakage exists will result in the introduction of small amounts of air into the cooling system, which may cause air locks and so a complete stoppage of flow. Generally speaking, such leaks will only be manifest when the motor is at rest, as the suction is sufficient to hold back the water when it is running.

RIGHTS IN UNPATENTED DESIGNS

Appeals Court Declares Imitation of Rushmore Lamps Illegal—Views as to Unfair Competition.

In the manufacture of automobile lamps, as well as in the field of other motor car accessories, there has for some time been a very delicate situation because of the similarity in design which the products of various makers bear to each other, and a decision rendered in the United States Circuit Court of Appeals, in New York in the litigation of the Rushmore Dynamo Works, of Plainfield, N. J., against the Manhattan Screw & Stamping Works, of New York, is illuminating as making clear the legal idea of how far imitation may be restrained when the article imitated is in some of its features not covered by design patents and the restraint is sought on the grounds of unfair competition.

An order was granted in the district court for a preliminary injunction against the Manhattan Screw & Stamping Works, preventing the latter from making lamps resembling the Rushmore "flare front" design and from using the words "flare front" themselves. An appeal from this order was taken by the defendants, with the result that the words "flare front" in lamp description were decided as being not subject to the exclusive use of the Rushmore Dynamo Works, but maintaining the latter company's contentions as to the exclusive right to the "flare front" design which it has made popular. That there are limits to the "unfair competition" argument to restrain competition, however, is plainly indicated by the decision on the appeal, which is as follows:

Before Coxe and Noyes, Circuit Judges and Adams, District Judge.

On appeal from an order granting a preliminary injunction enjoining the defendant, its officers, employes and agents "Not to manufacture, sell or use, exhibit or advertise any automobile lamp or lamps having enclosing cases or shells made in imitation of or resembling, or a colorable variation of, the Rushmore 'Flare Front' search light lamp exhibited to this Court herein and of which a sample has been offered marked 'Exhibit A,' except in so far as such lamps may be the genuine lamps made by complainant, and not to use in connection with any lamp made in imitation of or resembling or a colorable variation of said 'Exhibit A' Rushmore Lamp, the words 'Flare Front' and not to print or publish or have printed or published in catalogues or advertisements or elsewhere, any cut or representation of any lamp in imitation of or similar to said 'Exhibit A' Rushmore Lamp, and not to print or publish in any catalogue or advertisement or elsewhere the words 'Flare Front,' or similar words in connection with the representation of any lamp made in imitation of or similar to said 'Exhibit A' lamp, except in so far as such representation and such words may be used to advertise or in connection with genuine Rushmore lamps made by the complainant."

Hans V. Briesen, for Defendant-Appellant.
Alfred Wilkinson, for Complainant-Appellee.

Coxe, J.

In December, 1905, the complainant adopted a design for the shell of an automobile lamp and in the following January exhibited it at the exhibition of automobiles at Madison Square Garden, New York. This is the complainant's lamp in controversy. Its exterior is pleasing to the eye and it is unquestionably a high grade lamp, but there is nothing strikingly novel or ornamental about it. In general contour it resembles the search-light which has for years been in use upon excursion boats and vessels of war, the principal difference being in the addition, by the complainant, of the so-called "flare front," the glass front of the lamp being larger in diameter than the body of the lamp except as it flares out near the front to meet and inclose the glass. No patent has been granted to Rushmore either for a combination, for a new article of manufacture or for a design for the shell of the lamp. It is possible that had application been made a design patent might have been granted and sustained.

In West Disinfecting Co. vs. Frank, 79 C. C. A. 359, this court recently held valid a design patent for a somewhat similar structure.

The defendant is manufacturing a lamp which, though differing in several details of construction, unquestionably resembles in external appearance the Rushmore lamp. If a valid design patent has been issued to the complainant we have no doubt that the defendant's of difference are unimportant, we will consider the question involved o- on the theory that the shells of the two lamps are substantially identical.

The defendant has adopted "Phoebus" as its trade mark and its lamp is known to the trade as the Phoebus lamp. All of its lamps have conspicuously displayed on the top thereof a name plate with a black background inscribed "Phoebus, the lamp of Quality, Model 601, Manhattan Screw & Stamping Works, N. Y." The officers of the defendant deny that they, or any one connected with the defendant, have ever in any way represented their lamps as those of the complainant. There are allegations in the bill, made upon information and belief, that the defendant has palmed off its lamps upon innocent purchasers as the Rushmore lamps, but there is nothing in the affidavits worthy of the name of evidence to establish these allegations. The affidavits, in our judgment, also fail to establish an exclusive right to the use of the name "Flare Front." The complainant savs in his affidavit, "I am aware that what might be called 'flaring fronts' have been used on other forms of lamps entirely different in appearance from my Exhibit A lamp, for instance the old carriage lamps, but I am positive that I am the first who has ever used these flare fronts on any lamp similar in appearance to my Exhibit A." Assuming the correctness of this statement we do not think the fact that complainant was the first to put a flaring front on a shell of his design entitles him to a monopoly of these words. We regard them as descriptive merely and are of the opinion that an injunction should not issue at least until proof, more cogent than anything which now appears in the record, is presented, showing that they have acquired a secondary meaning.

So far then as the prayer for an injunction is based upon the use of the name "flare front" and the allegation that the defendant has actually deceived purchasers by representing that its lamps were made by the complainant, the most that can be said is that the questions are involved in doubt. This court has uniformly helu that an injunction should not issue in a doubtful case.

Hall Signal Co. vs. Railway Signal Co. 153 Fed. 907.

Cleveland Foundry Co. vs. Silver, 134 Fed. 591.

Hildreth vs. Norton, decided Feb. 11, 1908.

As we read the opinion of the judge of the Circuit Court he finds no actual fraud and no evidence that the defendant is now using the word "flare front." He says:

"Assuming that at the present time the defendant is not using the word 'flare front,' is not selling its product as Rushmore lamps, and is not using in any way either of these words or phrases, the question is whether plaintiff is entitled to be protected from unnecessary imitation of non-functional parts of his well known lamp. It seems to me that under the cases of Enterprise Manufacturing Co. vs. Landers, 131 Fed. Rep., 240, and Marvel Co. vs. Pearl, 133 Fed Rep., 160, he is so entitled."

We are thus confronted with the naked question of law—can one who manufactures and sells a well known article of commerce, like an automobile search light, inclosed in a shell of graceful, but unpatented design, maintain a bill for an injunction, profits and damages against a defendant who sells automobile search lights inclosed in a similar shell, with his name prominently appearing thereon as the maker, and who has never represented that his lamps were made by the complainant?

We feel constrained to answer this question in the affirmative upon the authority of Enterprise Co. vs. Landers, supra, and Yale & Towne Mfg. Co. vs. Alder, 154 Fed., 37. Both of these cases were decided by this court and we see no way to distinguish them, on principle, from the case at bar. We are of the opinion, however, that to answer this question in favor of the complainant carries the doctrine of unfair competition to its utmost limit.

If it be pushed much farther those engaged in trade will be encouraged to run to the courts with trivial complaints over the petty details of business and thus will grow up a judicial paternalism which in time may become intolerable.

This cause or onei nvolving the question at issue may be easily brought here on appeal from the final decree and heard at the next term. After the witnesses have been cross-examined we may be able to tell with much greater certainty whether the competition of which the complainant complains is produced by the similarity of the shells of the two devices or by the fact that defendant is selling its lamps at a much lower price.

It appears from the record that purchasers of automobiles belong to the wealthy class, who are not particular about the price paid so long as they secure durable and efficient machines. They are not the class of buyers who might purchase a padlock, for instance, after a casual inspection and it is not easy to understand how such fastidious buyers with the Phoebus name plate before them can be deceived into thinking that they are purchasing the Rushmore lamp.

If it should appear, after full hearing, that the effect of the injunction will be to stifle legitimate competition rather than to punish unfair competition we will not hestitate to dissolve it, but upon the affidavits now before us, the majority of the court is of the opinion that the case is controlled by the former decisions of this court.

The order should be modified by excluding from its provisions the prohibition against the use of the name "flare front" and, as so modified, is affirmed.

STODDARD-DAYTON ENTERTAINS

Many Pleasures Provided at Second Annual Convention of Agents—Matters of Mutual Interest Discussed.

Agents' conventions, which occur with increasing frequency from year to year, may be said to have the uniform purpose of familiarizing the selling organizations of the various manufacturers with the details of the products and selling plans of the coming year and of unifying the efforts of the various salesmen and directing them into the most efficient channels. In this respect all such meetings closely resemble one another. In detail method they differ according to the scope and efficiency of the companies holding them. As illustrative of the usefulness of these gatherings, which usually receive such curt notice from the press, and also as casting an interesting side light on the rapid growth of a concern which is very much alive to the possibilities of the automobile business, it is useful to record the doings of the second annual convention of the Stoddard-Dayton agents, held at the Ohio home of the Dayton Motor Car Co., and the cash register

Wednesday, Thursday and Friday of last week, 29th to 31st ult., were the days set apart for the formal proceedings. The program actually commenced on the preceeding Tuesday evening, when the public of Dayton was invited to view the setting of the forthcoming convention—and accepted in goodly numbers.

Primarily, this setting was an individual automobile show. The 1909 models—some 16 varieties, embodying various methods of mounting the five styles of chassis which compose the full line for next year—were shown in completed condition on the sixth floor of the new wing of the factory. Not only this, but the accessory adjunct which forms so important a part of every well ordered show, was well stocked with samples of the fittings and equipment which are to go on the new cars regularly, as well as some that might be included at the option of the purchaser. By way of rounding out the exhibit there were structural parts of the cars by the score. A sectional working model of the valve-in-the-head motor adopted last year, crank shafts and connecting rods in various stages of completion, even the dies and jigs by which they are formed, and various other parts and materials in raw and complete stages, served to make complete the display.

While full information as to the new models will not be forthcoming for a few days, it is possible to state that they will be known as: "A," "F," "K," "C," and "H," each distinguished by the prefix "9," to indicate the year of production. The first and the last two will be entirely new cars; the others improved forms of previous models. A striking point in this connection is that the design and construction of the cars will be strictly uniform. That is to say, practically three sizes of the same car will be produced, no difference in design, method or materials of construction other than such as may be determined by differences in power and weight being present. Thus the prospective buyer is to be offered the Stoddard-Dayton car. After examination he may choose the size best suited to his purse and fancy. For the man of moderate requirements there will be a wonderfully attractive little offering at a price to match. To make the line complete, a good variety of bodies also has been developed, bringing out a number of demountable combinations, and among them that promising idea the "baby tonneau."

It was on the same floor with this display that the formal sessions of the convention were held. Here, in the presence of chart and blackboard "first-aid" to the imagination were demonstrated the ideals upon which the present designs are founded. Here, also, occurred the usual discussions incident to purely "family reunions" such as pertain to the successful handling of competition, the fine points of marketing, prices, talking points, territorial boundaries, and the ever fruitful topics of equipment and accessories.

In these discussions unusual pains were taken to obtain an expression of opinion from all the agents as to the proper decision of such questions. It did not follow, as was explained, that the opinion of the majority would directly govern the policy of the company in laying its plans for the future, but it was given to understand that such considerations would weigh heavily in all determinations directly affecting the matter of sales.

In thus getting into closest touch with the ideas of the selling forces the real convention spirit was brought out in a way not possible where, as is sometimes the case, the manufacturer preserves the attitude of instructor only, and treats the criticism of the agents in the same spirit as their requests for instruction. Indeed, the spirit of co-operation here emphasized was manifest to a surprising degree throughout the entire meeting. Its outward indication is evidenced in the loyal attitude of agents and factory employes alike.

President C. G. Stoddard touched upon this spirit of loyalty at the banquet when he said that without the intense feeling of personal responsibility and fidelity to the company as shown to a striking degree by the forces at home and in the field, the rapid progress of the concern would have been an absolute impossibility

The banquet, which was tendered on Thursday evening at the Dayton Club, brought more than one forcible tribute to the unity of purpose which has been instrumental in building up in a quiet way a force which is very much to be reckoned with in the present stages of the industry. The ideal method of building an organization worthy of emulation was crystalized by R. T. Houk, of the factory force, who pointed to the fact that an organization can be complete only when every member realizes the importance of the particular duty assigned to him — no matter how insignificant it may appear—and is willing, even eager, to do his best to carry it on. Nor can an organization be complete when its leaders hesitate about ridding themselves of assistants who are not fully competent to carry on their tasks.

"The fact that a man is bad only in spots," he said, "ought not to justify his being retained for further trial or for use in a new position—an egg which is not fit to boil, don't do to scramble. It is all too easy to make excuses for retaining a man who is half good; he is a good fellow, he tries so hard, he is willing, or maybe he is handicapped in some manner beyond his control —but that is not perfection. And the perfect whole is composed of only perfect units. This is a relentless principle."

Another important point was brought out by E. R. Blaine, of the Blaine-Thompson Co., Cincinnati, who spoke of team work in advertising. "Here is a national broadside of magazine advertising," he said, "directed toward the general publicity of the product. It is destined to benefit the entire organization to an almost equal degree. But the agent who permits it to go by without grasping the opportunity of advertising himself locally as the representative of the company is missing a golden opportunity. The effect of this general work is entirely lost in his section unless the local man takes it upon himself to identify himself with the product. There must be team work among these widely scattered forces or half the effort will go for naught."

The convention was attended by three score and more of the regularly constituted agents of the company to whom were added a goodly number of invited guests, newspaper men and others who were provided with ample entertainment and a cordial welcome at the factory. Here it was plainly to be seen that the new cars constituting the "show" were neither dummies nor hastily completed models. From the stacks of assembled groups on the erecting floor clear down the line to the foundry every hand was busy with the 1909 product, already well on in the making.

Live "Ads" at British Race Meets.

Sharp rivalry in British trade circles has called forth various advertising dodges, some of them ingenious, some following out lines which have been found successful in other sorts of business. One firm of tire makers has lately resorted to the use of "sandwich men," a corps of whom parade about at race meets and other sporting events, each carrying the usual placard, in addition to which a tire casing is slung around his neck.

MILITARY VALUE OF AUTOMOBILES

General Grant Gives His Views to the Motor World—Some Inside History Explains Pine Camp Reports.

That automobiles are not only practicable for the needs of the army, but that their use adds greatly to the efficiency of fighting bodies, is the assertion of Major General Grant, who commanded the regulars and State troops at the recent manoeuvers in Pine Camp, New York. Incidentally General Grant refuted the statements that have appeared in the daily press to the effect that automobiles were not practicable for army purposes. When interviewed by a Motor World representative on the subject of automobiles for army purposes, the General said:

"The automobile is a necessary adjunct to the equipment of an army. Its uses are manifold in this connection, but its main and distinctive value lies in the fact that by its use a commanding general can keep in personal touch with his entire troops, which is not alone desirable, but necessary, since he must have absolute and accurate knowledge of all conditions as they exist among the bodies under his command.

"In the wars which have occurred up to this time, the man on whom rested the responsibility for the success or failure of a battle, largely was dependent on the reports of conditions brought to him by his subordinates. An army or an army corps on the field of battle, occupies an immense territory, they are spread over a large area and the outposts are many miles apart. The only way that one man could himself observe the different positions of his troops and the relation of these positions to each other, prior to the development of motor cars, was by riding about on horseback. This mode of traveling not only exhausted the vitality of the rider, but made necessary a more or less elaborate system of relay horses, and even under these conditions, the journey would occupy more time than, at a critical moment, should be given to such an inspection by a general whose responsibilities and duties are necessarily enormous. Incidental to this there also existed the drawback of the troops altering their positions during the two or three days that would be required to make such an inspection on horseback.

"But the automobile changes all this. In ten hours, even though the roads were in but fair condition, a distance of two hundred miles easily could be traversed. True it is that such a trip would be hard both on man and machine, but hardships are the main part of warfare, and where the disagreeable part is mitigated by the possibility of riding on soft cushions, shielded from the direct rays of a blood heating sun, or protected from a drenching downpour of rain, such a trip could be undertaken and accomplished and the results of it would at once become manifest by an increased efficiency of an army owing to its commander having seen the exact situation of his troops. Incidentally the moral effect of a visit from a major general, on subordinate officers and the men of their commands is excellent and tends to increase the feeling of personal responsibility in the man. And this is a keynote of success. In short, the automobile furnishes the means of personal contact between the leaders of an expedition and the men on whom the success of the undertaking depends, and this mutual acquaintanceship is of immense value."

General Grant then was asked his opinion of the value, for army purposes, of motor trucks. There was no hesitation in the response which came in the characteristic slow way, a trait of the Grant family.

"The automobile truck cannot successfully compete with the government mule. The much despised, much caricatured army mule is equal to about 50 horsepower in an automobile, when it comes to taking a heavy load up a steep hill over bad roads. I don't want to be quoted," continued the general, "as stating with mathematical precision, or as a result of studied experiments that one mule equals 50 horsepower under the conditions I named, but I mean to illustrate that the mule is a reliable machine of known power when a hard hill climb is to be encountered, and we army men will need a lot of convincing before we will agree that he should give way to a high powered gas engine.

"For ambulance service and for the freighting in connection with the habitation of an army post, the motor vehicle, the light or even heavy truck, is ideal. But at this time I know of no motor truck suitable for the needs of the army on the march or on the battlefield."

Asked about the authenticity of certain adverse reports which have appeared in the newspapers, in regard to the service rendered by motor vehicles in connection with the recent Pine Camp manoeuvers, he said:

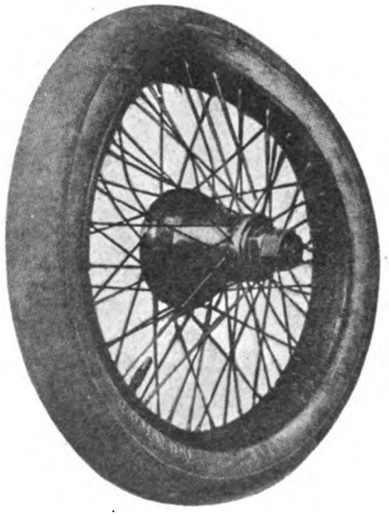
"The reports, in a measure, were true, but they failed to state why or under what conditions the machines were not practicable for our use, and I'll tell you the inside history of my automobile experiments in Pine Camp. This is the history which formed the basis of this adverse comment. There was some difficulty with the cars, but about 90 per cent. of it was due to the chauffeurs. The cars were all right, the machinery worked well; and when I was a passenger in the car there was no trouble, no delay, no break, everything was all right. But when I would order the car on the following morning, I would be told that something was out of order. I wondered how accidents could occur while the car was standing idle in its shed, but no one seemed able to tell me, so I concluded that may be this thing they call 'joy riding' was responsible for the trouble. Now 'joy riding' is an easy thing for an army officer to overcome. I merely detailed a sentry with a loaded gun to guard that car. I told him not to let any one touch that machine without an order over my signature. Chauffeur and every one else was barred, and immediately conditions were changed. When I ordered the machine it came. I suffered no delay, no mishap; and only two or three punctures caused a temporary layup. The armed sentinel is an excellent insurance of motor car efficiency."

"What do you think is the best design for army purposes?" asked the interviewer.

"I believe that the most useful car would be one having a light, strong body, designed to carry four people. Such a car would carry, in addition to the chauffeur, the general and two aides-de-camp. The car should be high powered and carry a large quantity of fuel. There should be some arrangement for transporting a little baggage with blankets and other essentials to 'part comfort' if sleep by the roadside became necessary. If possible there should be some devise incorporated in the tires to prevent punctures, even though resiliency of the tires was effected by the introduction of a steel band or some similar contrivance, the added discomfort to the riders would be compensated for by immunity from delays. That is about all that it needed. In Pine Camp I used a seven passenger car, it was very comfortable and very delightful, but it was too luxuriant for military purposes."

"One thing more," said the interviewer, as he prepared to leave, "What about 'the chauffeur question;' would you always have to guard your machines to prevent 'joy riding?'"

"Hardly," said the General, and he smiled. "The machines in Pine Camp were operated by civilians,. My machine was guarded and gave good service; the one used by Colonel Glenn was not guarded and gave less satisfactory results. When the cars are owned by the army they will be operated by men in the service. We now are training men of the engineers' corps to handle automobiles, and I greatly doubt if soldiers will disobey orders with the same nonchalance that civilians disobey them. I think the 'chauffeur problem' would not present insurmountable difficulties."



That the General's belief in this solution of the question is well founded, is shown by the results obtained by President Roosevelt, who has for his use two White steamers which the government owns. The drivers of these machines are, or rather were, chauffeurs who were trained by the White Co. These men now are sworn in as members of the secret service and are detailed to operate the machines. The uniform reliability of the cars may be taken as an evidence that they are handled properly and it is safe to say that a secret service man would find it more serious to disobey an order than would a civilian chauffeur.

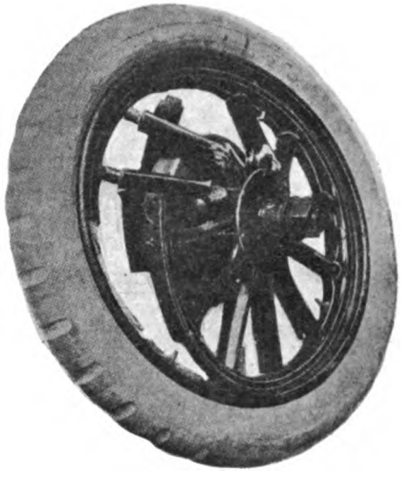
RESISTANCE TO SKIDDING STRAINS

Comparative Tests of Wood and Wire Wheels—The Method Employed and the Results Obtained.

Wire wheels, though not in vogue in this country within the past few years, are still employed in England to a considerable extent, one popular mode of application being in the Rudge-Whitworth detachable arrangement, which is the idea of the demountable rim carried to its extreme application. The considerable use of this affair

WIRE WHEEL SHOWING RESULT OF TESTS



has served to keep alive the old controversy as to the relative strengths of wood and wire wheels, a series of tests recently carried out by the makers of the device in question, forming a useful and rather surprising contribution to a subject which has been permitted to languish elsewhere for some little time.

Four wheels were tested, according to the Autocar, from which the accompanying illustrations are reproduced—one R.W. wire and one wood front, and one R.W. wire and one wood back. Both wire wheels were of the detachable variety. The size of the front wheels was 870x90 mm., and of the back wheels 880x120 mm., the tire pressure being about 80 pounds. The weight of a set of four Rudge-Whitmore wheels is 101.4 pounds, and of the four inner hubs is 48.3 pounds, making a total of 149.7 pounds. The weight of a set of four wood wheels is 179.84 pounds.

The apparatus employed, was really a crude form of pendulum impact machine. A pendulum was hung from the ceiling of one of the shops and sustained a weight of about 450 pounds. The wheel to be tested was mounted on a massive steel mandrel turned down at the end to take the wheel hub, and anchored to a solid bed of concrete. The pendulum bob was adjustable for height, so as to bring it opposite the rim flange of the wheel under test. Pulley tackle was used to haul the bob away from the wheel, and was fitted with a simple device for releasing the bob, which swung with great force, over a distance of about 6 feet, up against the wheel.

After each wheel had been tested in this manner, it was again mounted on the mandrel, but with the point which had been struck by the bob at the bottom, so that the blow would be struck at a point diametrically opposite to that at which it was struck in the first test.

The formula used in calculating the

WOOD WHEEL SHOWING RESULT OF TESTS

energy imparted by the bob at each blow was:

$$E = \frac{W}{2R} L (L - 2d),$$

where W = weight in pounds of pendulum bob (about 450 pounds); L = distance in inches between the rim of the wheel and the side of the pendulum bob before being released (about 6 feet); d = distance in inches betwen the rim of the wheel and the side of the pendulum bob when hanging free (about 3 inches); and R = length between point of suspension of pendulum and center of gravity of bob (about 16 feet).

The relative merits of the two wheels to withstand what would be equivalent to violent side-slipping on the road were judged by observation of the effect of each blow, measurement of the permanent deflection at the point of impact, and the amount of energy imparted at each blow. These results are given herewith in tabular form, the results of the first test, i. e., hitting the side of the new wheels, being given first, followed by the results of the second test—hitting the damaged wheel at a point on the same side, but diametrically opposite to the point at which the blows in the first test were struck.

From these tables it will be seen that the energy imparted, in the case of the front wheels, to the wire wheel, although con-

WOOD AND WIRE WHEELS COMPARED

siderably greater than imparted to the wood wheel, caused a deflection of the wire wheel .16 inch less than in the case of the wood wheel. Although this difference is small, it must be remarked that the damage was much more "local" than in the case of wood wheels, the blow affecting only that part of the rim and spokes in the region of the point of contact of the bob and the spokes diametrically opposite. The damage was chiefly manifested by the spokes breaking away under tension from the heads at the hub, and in a few cases from the nipples at the rim. In only one case did a nipple pull through the rim.

The damage to the wood wheel, on the other hand, spread erratically over the whole wheel, manifesting itself by split felloes, also spokes pulling out of the felloes or breaking across at the dowel in the

THE TESTING APPARATUS.

felloe. These general effects were observed throughout all the tests. It was also observed that the wire wheels gave gradually to the impacts, and did not collapse suddenly, as was the case with the wire wheels. This was most noticeable in the case of wheel C (first test.)

After the second blow it was found that the only damage incurred was four broken spokes. The third blow shattered the wheel, the felloe splitting in two the whole way round and the spokes breaking. This wheel is shown in one of the illustrations. The results of the second test show that the wood wheel was fairly able to withstand blows at a point diametrically opposite the first blows —in fact, better than was expected—but nevertheless it was surpassed by the wire wheel, as is well exemplified in the foregoing tables of the second test, especially in the case of the wheel D (second test), which sustained four normal blows and a final smashing blow of 7 ft. 3 in., with no further damage to the wheel but three more spokes broken. Its wood companion wheel C was destroyed during the first test.

"Summing up it should be obvious that the wire wheel is equally able to beat the wood wheel in the matter of heavy sudden side blows, as in the many other comparative tests which it has undergone in company with wood wheels," says the Autocar. "These tests again serve to show that detachable wire wheels, properly built, are far superior to wood wheels for all-round year use."

To Prevent Bolts from Loosening.

It is a common failing of so-called stove-bolts to become loosened after a comparatively short amount of use in securing wooden and metal parts together, as in the case of the top irons and the metal work of the dash board. The failure is apt to come through the loosening of the conical head in its wooden seating, thus permitting the nut to obtain enough slack to rattle loose on its thread. A simple way of preventing this difficulty is to enlarge the slot across the head of the bolt, cutting the ends pretty deep by the aid of a file, and then bend over a short length of copper wire, which is of just the size to fit nicely in the slot. In this way a couple of ridges are formed on either side of the head, which effectively prevent it from turning so long as a reasonable amount of pressure is brought to bear upon it.

Endurance of the Ball Bearing.

It is commonly conceded that the life of ball bearings, when properly made and used, is far beyond that of the plain type. Just how long a well made bearing of the annular type will last under normal usage is difficult to say—probably longer than any other portion of the car, when applied to automobile mechanism, for instance. An interesting bit of testimony in this connection is supplied by the Hess-Bright Manufacturing Co., Philadelphia, Pa., in regard to the condition of a set of five bearings taken from the transmission of an automobile maker's demonstrating car. After more than 50,000 miles of service, the bearings were returned to their makers for examination. Only two were in a condition to indicate the advisability of refilling them with slightly larger balls, the other three appearing to be about as good as new.

Slamming the Tonneau Doors.

One of the errors to which nearly all automobile users are addicted is the slamming of tonneau doors. Probably the habit comes from the accepted practice of slamming the doors of broughams and other horse drawn vehicles which are so constructed that it does not injure them. With the ordinary type of touring car body, however, the door frames are not braced with sufficient solidity to withstand successfully the effects of repeated shocks from the door. As a result the frames of many bodies become loosened before their time. It is a good rule for the car, as for the house, that attention be paid to the injunction, "don't slam the door."

Looking After the Valve Tappets.

Engines which are provided with adjustable valve tappets have the advantage that the distribution of the gases in the cylinders may be regulated to absolute synchronism. There is this disadvantage to the arrangement, however, that the adjustments may work loose if not properly secured in the beginning. On this account it is well to make sure that the check nuts holding the tappet adjustments are kept tight at all times, and that any apparent irregularity in the output of the different cylinders be made cause for going over the timing gear.

Peculiar Construction in Non-Skid Tire.

Because of the vigor with which it is being introduced in England, Cryder & Co., of New York, are importing from Great Britain the Kempshall all-rubber, non-skid tire, the unusual tread construction of which is claimed to possess peculiar merits in preventing side slip or loss of traction. As shown in the accompanying illustration, the tire has a series of circular depressions in the tread, while in the middle of each of the shallow pits so formed is a turret-like

KEMPSHALL NON-SKID TIRE

rubber stud of generous proportions. The circular resisting edges and the central turrets are credited with great effectiveness in checking slipping or sliding on the greasiest road surfaces. The further quality of cooling the tread in high speed running is also ascribed to this construction since it presents a great area of radiating surface. In the building of the tire certain special features are claimed, including the use of alternate layers of rubber and canvas so disposed as to give maximum strength.

Trouble from Valve Stem Expansion.

That puzzling engine difficulty which is manifest by a loss of compression when the cylinders are hot, when they are known to have been tight when cold, is readily explained by the expansion of the valve stems during the warming process. Unless a proper amount of clearance is allowed between the ends of the stems and the tappets, this may be sufficient to prevent the valves from setting. This difficulty has befooled the wisest of drivers.

Many Makers Using Shock Absorbers.

Shock absorbers as part of the regular equipment for the 1909 cars of the George N. Pierce Co. are announced by the Hartford Suspension Co., of New York, whose Truffault-Hartford absorbers are to be used for the fifth consecutive year. In all, 20 concerns are using Truffault-Hartford shock absorbers as equipment.

POSITION OF THE SPARK PLUG

Its Effect Upon Resulting Power Output as Shown by Experiments—Variations Caused by Engine Speed.

One of the most enlightening chapters of experiment ever presented to the automobile industry resulted from the investigations of a year and a half ago from which W. Watson, the English scientist arrived at the, then, startling conclusion that the "fatness" of the ignition spark had absolutely no effect on the power output of the motor. Supplementing these investigations, a second article later appeared in which the influence of the character of the spark on the power developed was further treated. A third instalment has now appeared from the same source, in which the effect of the position of the spark plug upon the resulting power output is considered.

In the former experiments a low compression engine was employed, and one which, furthermore, was not available for speeds over 900 revolutions per minute. In the engine upon which the latest trials were made, a compression pressure of 87 pounds was maintained, while the machine was capable of being run satisfactorily at speeds up to 1,600 revolutions per minute. In reference to the apparatus and method of test, Mr. Watson says:

"The engine used is a four-cylinder one, the bore being 85 mm. and the stroke 120 mm. The ignition is by means of either a high tension magneto (Lacoste 1906 type) or a single coil and high tension distributor. The indicator diagrams . . . . were all obtained, except when otherwise noted, from one cylinder (No. 2) by means of the optical indicator used in the previous series of experiments.

"The previous experiments having indicated that the position of the sparking plug had an important bearing on the power developed, two spark plugs were fitted, one over the inlet valve (the usual position) and the other over the exhaust valve, the valves in separate pockets on opposite sides of the combustion space. These spark plugs could be used in series, so that sparks occurred simultaneously in the two pockets or either could be used alone, the change being made by means of a switch." . . . .

In the first test under discussion, with the motor running at 640 revolutions per minute, it was observed that only slight differences in power were obtained. With the spark over the inlet valve the indicated horsepower per cylinder was 2.8, the corresponding value of the mean effective pressure being 83.9 pounds per square inch. With the spark over the exhaust valve the indicated horsepower was 3.0 and the mean effective pressure 90.0 pounds per square inch. Finally, with both sparks occurring simultaneously, the indicated horsepower was 2.9 and the mean effective pressure was 86.7 pounds per square inch.

When the speed of the engine is increased to 1,100 revolutions per minute a marked difference is obtained with the different sparks. In the first place, when the charge is fired at the two points the work obtained is very considerably greater than is the case when only one spark is used. Thus:

	I.H.P.	M.E.P. lbs. sq. in.
Spark over inlet valve.....	4.6	79.4
Spark over exhaust valve ..	4.6	79.1
Both sparks	5.2	90.5

Further, a curious difference in the conditions of the gases in the cylinder during the working stroke will be seen. Thus the expansion stroke shows that well marked pressure waves existed in the cylinder during nearly the whole of the stroke. In the case of the spark over the exhaust valve, these waves are even more well marked. When, however, the two sparks occur simultaneously, practically all signs of waves in the cylinder disappear. It would thus appear that when the combustion of the charge is started in one of the pockets only, waves are set up which pass backward and forward across the cylinder. When the charge is fired in both pockets, then the waves would appear to interfere with one another.

When the speed is further increased to 1,620 revolutions per minute, the differences are even more marked, as is shown in the following table:

	I.H.P.	M.E.P. lbs. sq. in.
Spark over inlet valve	6.5	76.3
Spark over exhaust valve ...	6.4	75.1
Both sparks	7.3	85.7

At a speed of 1,100 revolutions per minute, the magnitude of the difference obtained with the sparks depends to a certain extent on the strength of the mixture. When the carburetter is adjusted so as to give the best mixture at this speed, the improvement obtained by using the two sparks is not quite so great. At higher speeds, such as 1,600 revolutions per minute, however, the improvement obtained with the two sparks was most marked with all strengths of mixture.

The improvement obtained when using both sparks at the higher speeds is due to the more rapid ignition of the charge. The fact that the advantage of igniting the charge in both pockets is greater the greater the speed is best illustrated by the indicator card from which it is readily apparent that at high speeds the more rapid rate of inflammation of the charge results in a higher pressure. For it is only at high speeds that this rapidity of burning of the charge is of such vital importance. With slow speeds it is quite possible that the more rapid burning obtained with the two sparks may be a disadvantage, for in practice the spark is often too far advanced at slow engine speeds, and hence the comparatively slow burning obtained when only one spark is used partly compensates for the too great spark advance. Such a case will occur if, as is sometimes done, the timing of the magneto is fixed. Some makers adopt this arrangement, the argument being that the spark occurs earlier and is much "fatter" when the armature is rotating rapidly, and hence that an automatic adjustment takes place.

Two tests, A and B, were made at 640 revolutions per minute with magneto ignition. In the first case the diagram was obtained using at this speed the spark adjustment which gave the best result at 1,600 revolutions, while diagram B was obtained by retarding the spark. It will be at once observed that if the magneto is adjusted to give the maximum power when the engine is running fast, then when the engine is running slow the power will fall off considerably, and there will be a tendency to knock. The difference in power is considerable, being nearly 14 per cent:

	M.E.P.	I.H.P.
In A	86.0 lbs. sq. in.	2.9
In B	97.4 lbs. sq. in.	3.3

In this connection the opportunity was also taken to make some further comparisons between the effects obtained with a coil and with a magneto, and it was found that with weak mixtures there was a decided improvement obtained by using the intense spark given by the magneto.

"Some insight into the reason why some engines are found to give so much more power with the magneto ignition was, however, given by the present engine," says the author. "The magneto has a wipe contact maker which is used with a single coil, the same high-tension distributor being employed as is used with the magneto. When this contact maker is used the diagrams obtained at a speed of 640 revolutions per minute from each of the four cylinders . . . . showed that the timing is hopelessly wrong, for while in cylinder 2 the spark advance is about right, in the other three cylinders the spark occurs much too late, and the diagrams illustrate the corresponding loss of power. At higher speeds the effects of the error in timing are very much more marked. Instead of attempting to readjust the wipe contact maker, a single make and break was fitted up on a counter shaft, and this shaft was driven at twice the engine speed. In this case the same make in the primary circuit of the coil is used for all four cylinders, and the only variation which affects the timing of the sparks in the different cylinders is the lag of the trembler blade, which may vary slightly from instant to instant, for, although the same trembler is used for all the cylinders, yet since the vibrations set up in the trembler during one 'make' will not in general have entirely died out when the next 'make' occurs, the rapidity with which the first trembler 'break', i. e., the first spark at the plug, occurs, will in a measure depend on the phase of the vibration of the trembler existing when the second 'make' occurs."

BIG MASSACHUSETTS REGISTRATION

State Income from Motor Vehicles More Than $100,000 for First Half of Year—Many Non-Residents Registered.

Massachusetts is deriving from the registration of motor vehicles a bigger income than ever has been yielded from that source. Cars have been registered recently at the rate of about 50 each day, and the total number so far since January 1 has been 15,767. Returns for the first half year, which have reached the state treasurer, show that the fees collected in connection with the automobile activities by the Massachusetts highway commission since December 1 last, amounted to $100,782. This is more money than the automobile registration business has ever before brought in within such a short period. About 10 per cent. of the cars registered recently have been those of owners having residence in other States, but who have been coming into Massachusetts with their cars for tours or for a stay on a summer outing. About 300 registrations were reissues.

Since January 1, 366 dealers' licenses have been issued; 1,630 motorcycles registered; whereas for the corresponding part of the year 1907 the number of automobiles registered was only 4,953; of motorcycles, 535; and dealers' licenses, 58. The change in the law has had a good deal to do with the increase in the figures; still there has been without question a substantial gain in the number of cars used and operated in the State. A large gain is also recorded in the number of operating licenses issued. Up to the end of July of last year, 3,293 private operators and 3,977 professional chauffeurs had been licensed. This year, since December 1 last, the time of opening the official year's record, the total of private operators has reached 4,057 and of professional chauffeurs 4,480. It is worth noting that out of slightly under 2,000 new applicants for examination for professional chauffeurs' licenses the commission's examiners rejected about 30 per cent.

A new fee introduced this year is the 50-cent charge for duplicate sets of certificates for either cars or operators. This was authorized by the new law as a means of heading off what had grown to be a positive abuse. Operators and owners, losing their papers through mere carelessness, would run to the highway commission's offices for duplicate sets. So many of these requests came in that often the time required for getting out the duplicate was equivalent to the services of one clerk for hours on a stretch. The issue of hundreds of duplicates in this way made an appreciable increase in the office expense, and it was felt that a tax on the carelessness that made it necessary would be only fair. The only exemption from the fee is for police and court officers who need duplicate sets of certificates for handling cases in court.

New York's Automobile Revenue Shrinks.

Figures given out by the Secretary of State of New York show a falling off in receipts from automobile certificates. For the first six months of 1908 the receipts of the office are $900 less than the receipts of the first six months last year. Up to date the automobile department registered 8,245 automobile owners, as against 8,519 for the first six months of 1907. There is an increase noted in the number of chauffeur licenses issued, the number being 5,247 as against 5,191 for the first six months of last year.

There is also a decrease of 156 in the number of new companies organized in the State from January to July. The fees are heavy, however, and foot up more than $60,000 for six months. The fees in the motor vehicle department are also quite satisfactory, amounting to more than $27,000. For the period covered by the report the number of new corporations formed in the State is 6,634, the most of them being from New York and Brooklyn, with Buffalo, Rochester, Syracuse, Utica, Troy and Albany ranking in order named. The majority of automobile owners registered from Greater New York, with Buffalo and Syracuse and Rochester a close second, Utica and Albany following.

GLENCOE IN MOTORPHOBIC FRENZY

Chicago Suburb Engaged in Bitter War for Continuance of "Traps"—Automobilists Fighting for Fair Play.

Out Chicago way "there's blood on the face of the moon." Bitter war is raging with the village of Glencoe on one side and the Chicago Automobile Club on the other. Legal machinery is in active operation and victims from each side are tangled up in the gearing. The automobilists are threatened with a variety of things, the village constables are threatened with doses of cold lead, and the village itself is threatened with bankruptcy. The hostilities began several weeks ago, as reported in the Motor World at the time, when Special Policeman Frank H. Moor, failing to halt an automobile driven by Thomas P. Henderson, fired several shots from his revolver, one of which struck Miss Buena Stribling, who was one of the passengers in the car, and who fortunately was not injured, the bullet glancing from a button on her dress waist.

Moor has been indicted by the grand jury on a charge of assault with a dangerous weapon; Henderson has been fined by Magistrate M. T. Lane, of Glencoe, for overspeeding, and is under a charge of "assault with intent to commit murder," in that he attempted, as alleged, to run over Moor with his automobile; the automobilists are after Lane's magisterial scalp, and one of them has anonymously notified Lane that if the village cops do any more shooting there will be rifle shots in return; the automobile club of Kenilworth has joined forces with the Chicago club to make war on "speed traps"; the Kenilworth authorities are in sympathy with this movement; the Glencoe authorities are drumming up pugilists in Chicago to knock the blocks off the pickets placed by the automobilists to give warning of the "traps"; water wagons and other obstructions are to be wheeled into the path of refractory scorchers; a gold medal for "heroism" is to be conferred on Special Policeman Moor; this and a lot of other things; and the conservative people of Glencoe are wondering who is to pay for Glencoe's share of the hullaballoo.

The legal amenities in the matter, largely tinctured with acerbity, are under the direction of Village Prosecutor Morton Culver on one hand, and Sidney Gorham, secretary of the Chicago Automobile Club, on the other. The two lawyers have had some snappy colloquies at several of the various hearings that have been made necessary by the cross fire of legal proceedings and both are in for a fight to the finish. Personally, however, the two are slinging their wordy arrows at each other without any personal venom on the tips. It may be that out of the chaotic conditions there will come a "modus vivendi" to be maintained by an observance of the speed laws on the part of motorists, and by a sensible and reasonably tolerant executive of the law by the village authorities. Meanwhile the controversy is furnishing column stories for the Chicago papers.

Applying Speed Limit to Street Cars.

That speed limitation is not intended to apply only to automobiles and motorcycles, at least in New York City, was evidenced on Sunday night, 2d inst., in the arrest of Martin Davy, a motorman on the Columbus avenue and Broadway line of street cars. Davy was made a prisoner during the night by Detectives Lehane and Coleman, of the West Sixty-eighth street police station. In the night court they told Magistrate Harris that they timed the car from Seventy-seventh street to Seventy-ninth street on Columbus avenue, and it went at the rate of 18 miles an hour. From Seventy-ninth street to Eighty-first street the car covered the distance at a speed of 21 miles an hour. Magistrate Harris paroled Davy for examination in the West Side Court. Many complaints have been received by the police of the high rate of speed maintained by the cars in the upper section of the city.

Captures Jury by Clever Defense.

By a defense that certainly is entitled to be considered clever, David Pryor avoided conviction on a charge of overspeeding within the corporate limits of Uvalde, Tex., the other day. His trial occupied two days and the case was decided by a jury which was convinced by the double contention that the prosecution could not prove that Pryor was driving the car because he was going so fast that no person could identify him; and that if really the car in question was his car it was being used without his knowledge or consent. Ten of the twelve "good men and true" in the jury box acquitted him by a majority verdict.

Automobiles Connect Texas Towns.

On Monday, the 27th ult., a new automobile service between Temple and Marlin, Texas, was inaugurated. The route will be through the towns of Oenaville, Blevins, Bellfalls, Chilton, Mooreville, and several very small places, a total distance of 35 miles. The enterprise is backed by J. F. Robinson, of San Angelo, who for some time has been operating a similar service between San Angelo and Big Springs. The new line will permit a saving of a full day's time between the terminal points.

Abington Gets Easy Money.

Local activity in the suppression of automobile speeding has been the cause of bringing into the little township of Abington, Pa., the tidy sum of $800 since the first of May. During that time, no less than 60 fines have been administered, ranging from $10 to $55, 57 cases have been dismissed, fines suspended in 20 cases, and warnings given in no less than 162 other instances.

FREEING PARKS FROM OILY ODORS

Enforcement of Anti-Smoke Rule Begun with Vigor—Automobiles with Trails of Smell Kept Out.

Enforcement of the new anti-smoke regulation of the New York department of parks was begun on Saturday, 1st inst., and 17 arrests were made in Central Park. Three of the victims were operators of sight-seeing cars. Of the entire number, 11 were discharged with a reprimand by Magistrate Moss in the Yorkville court. Six who were arrested after the Magistrate had adjourned court for the day, were in Yorkville Court on Monday and had their cases adjourned. Magistrate Moss announced that if the Park Department could not furnish more evidence than had been produced in the cases of the men who had been discharged, he would dismiss all the cases that are brought before him.

Only three arrests were made in Central Park on Sunday and the victims were drivers of motor cabs, two of whom pleaded ignorance of the new rule. Hundreds of gasolene vehicles were "shooed" away by the police at the park entrance. Lieut. Hefferon and 30 mounted policemen were on hand from early morning until midnight, and they did their best to keep chauffeurs from violating the new rule. Hundreds of machines, some public, some private, would have entered had it not been for the warnings of the mounted men. All who were stopped told the policemen that they had not heard of the new rule.

Some of those who were halted at the entrances and turned back were inclined to take offense at the insinuation that their automobiles were ill-smelling affairs. There were some heated arguments between such owners and the policemen, and several times Lieut. Hefferon was called on to pass upon the machines in question. In a few instances the machine under discussion was allowed to enter the park. But in most instances the decision of the policeman who had halted the machine was upheld by the Lieutenant.

But, in spite of the large number of automobiles which were turned back from the park, there were large numbers of motor cars to be seen on the park drives all day Sunday. They did not leave an odor of gasolene, however, and consequently escaped being included in the class regarded as a nuisance.

The park authorities say that the smell which many of the automobiles emit is entirely a needless nuisance, and that it usually arises from the fact that the mechanicians allow the lubricating oil to leak. This can be easily prevented. The leaking oil, coming into contact with the heated parts of the machine, sends out an odor which is far from pleasant.

The Brush Runabout EFFICIENCY RUN

Started Last Saturday

INTRODUCING THE

MODEL B BRUSH RUNABOUT

FOUR runabouts and one delivery car started from Detroit Saturday afternoon, as follows: No. 1 for Boston, No. 2 for Washington, No. 3 for Kansas City, No. 4 for Minneapolis, No. 5, delivery car, for Milwaukee and return. Each car takes a roundabout route in order to take in a large number of good towns and demonstrate and exhibit the car in each one. With time taken out for demonstrating, it is expected that only about 90 to 100 miles a day will be covered, the total distance for each car being about 1,500 miles.

Car No. 3 will continue from Kansas City to Denver, and will then attempt the climb to the top of Pike's Peak, a feat which, we understand, no automobile has yet accomplished under its own power.

At present writing (Tuesday) all cars are running ahead of schedule, with no trouble reported.

A booklet will be issued at the close of the run giving gasolene and oil consumption, repairs, adjustments, mileage and other data. Send your name and address for it.

This run is intended to help our present agencies, interest new ones, and in general prove beyond a doubt that the Brush Runabout is what we claim for it—a car for work, not worry—a patient, ever-ready, never-tiring servant, quick, lively, easy to start, absurdly economical to run, requiring the minimum attention and giving the minimum trouble.

The Model B has much more graceful and in-style lines than the old model—divided seat, running board and winged fenders. WATCH IT!

The Week's Patents.

887,067. Engine Starter. Clyde J. Coleman, Rockaway, N. J., assignor to Conrad Hubert, New York, N. Y. Filed Aug. 19, 1905. Serial No. 274,819.

1. An engine starter comprising a power storing device, a ratchet member connected thereto, and a rotary pawl carrier connected with the engine, the ratchet member having two oppositely facing ratchet teeth and the pawl carrier having a centrifugal starting pawl co-operative with one ratchet tooth and movable by centrifugal force out of engagement therewith and a centrifugal power storing pawl co-operative with the oppositely facing ratchet tooth and movable by centrifugal force into engagement therewith.

887,093. Transmission Gearing for Automobiles. Ernst G. Hoffman, New Rochelle, N. Y. Filed Dec. 9, 1907. Serial No. 405,686.

1. In a motor vehicle, the combination of a spring supported body, an axle, a road wheel journaled upon the axle, driving mechanism supported by the body and comprising a driving wheel mounted upon a substantially longitudinal axis and a driven wheel mounted upon a transverse axis with freedom for oscillation about said longitudinal axis, and operating connections between said driven wheel and the corresponding road wheel.

887,094. Motor Vehicle. Russell Huff, Detroit, Mich., assignor to Packard Motor Car Company, Detroit, Mich., a Corporation of West Virginia. Filed Aug. 21, 1907. Serial No. 389,561.

1. The combination with a motor vehicle frame, of a fuel tank arranged transversely on the rear end portion thereof, and one or more metal straps for securing said tank, each strap comprising two parts, hinged together, one of said parts extending over the tank and downwardly on one side thereof, and the other part extending downwardly on the opposite side of the tank, the ends of the strap being suitably connected to the frame.

887,159. Process of Making Flexible Wire Shafts, Hartwell W. Webb., Newark, N. J., assignor to Webb Manufacturing Company, Newark, N. J., a Corporation of New Jersey. Filed March 26, 1907. Serial No. 364,735.

1. The process of making a flexible shaft out of one or more strands of wire, which comprises the following steps: first, winding one or more strands of wire upon a mandrel; second, removing the mandrel; third, winding one or more strands of wire upon the first helix as a mandrel in a direction opposite to that in which the wire forming said first helix was wound; fourth, stretching the shaft so formed lengthwise to an extent slightly beyond the elastic limit of the structure as a whole.

887,160. Flexible Wire Shaft. Hartwell W. Webb., Newark, N. J., assignor to Webb Manufacturing Company, Newark, N. J., a Corporation of New Jersey. Filed Feb. 8, 1907. Serial No. 356,449.

1. A flexible shaft comprising in combination two helical coils of wire wound one upon the other, each coil of each helix being separated by a slight distance from the adjacent coils of the same diameter and from the adjacent coils of the next inner or outer helix.

887,165. Spring Suspension. James C. Whittle, Flint, Mich. Filed Feb. 25, 1907. Serial No. 359,239.

1. The combination with an elliptical spring, of toggle levers connecting the members of said spring, and means for attaching the connected ends of the said levers to a sill movable longitudinally of the sill adapted to transmit lateral movements of the sill in either direction parallel to the plane of the spring to the said lever ends.

887,184. Universal Joint. Charles A. Brewer, Noroton Heights, Conn. Filed Aug. 23, 1907. Serial No. 389,811.

1. A device of the character described, comprising two trunnioned heads, and a coupling therefor consisting of inner and outer members having an annular lubricant chamber between them, the inner member comprising two halves with tongue and groove meeting faces and having trunnion bearings which cammunicate with the lubricant chamber, the outer member inclosing the two halves of the inner member and holding them assembled, annular receptacles to catch or detain escaping oil being formed each side of the lubricant chamber.

887,227. Dust Removing and Exhaust Device for Automobiles. Peter N. Ramsey, New York, N. Y. Filed March 14, 1902. Serial No. 98,145.

1. A motor vehicle having a tube extending longitudinally of and below the vehicle body and open at its front and rear ends and having its discharge of substantially the width of the vehicle body and positioned to blow away the dust and dirt rising behind the vehicle.

887,237. Gas Engine. Harris T. Dunbar, Buffalo, N. Y. Filed March 26, 1907. Serial No. 354,622.

1. A gas engine comprising a cylinder having a fuel port and an exhaust port, and a piston arranged in the cylinder and having a spiral guide way whereby the fuel is caused to whirl in said cylinder, substantially as set forth.

888,374. Explosive Engine. Henry O. Westendarp, Lynn, Mass., assignor to General Electric Company, a Corporation of New York. Filed April 14, 1905. Serial No. 255,510.

1. In an explosion engine, the combination of a cylinder having exhaust ports and separate fuel and air admission ports at its forward end, a piston in the cylinder which moves over said ports to open and close them, a carburetter connected with the fuel admission ports, means for supplying compressed air through the air ports while the exhaust ports are open and also for supplying it to the carburetter to produce a fuel charge therein under pressure, and means which permits the fuel charge to pass from the carburetter to the cylinder after the exhaust ports are closed.

888,405. Motor Vehicle Driving Mechanism. Joseph P. Lavigne, Detroit, Mich., assignor to The Blomstrom Manufacturing Co., Detroit, Mich., a Corporation of Michigan. Filed June 12, 1907. Serial No. 378,674.

1. In a motor vehicle driving mechanism, the combination of a drive shaft actuated by the motor and supported in vertical bearings, a friction disc at the lower end of said shaft, a longitudinally disposed driven shaft below the drive shaft, positive drive connection between the rear end of said shaft and the rear axle, a frame in which a portion of said shaft below the friction disc is journaled, a friction pulley shiftable upon said portion of the shaft and adapted to rotate the same and means for raising and lowering the frame.

888,487. Carburetter. Charles R. Greuter, Wilkes-Barre, Pa. Filed June 5, 1906. Serial No. 320,322.

1. A carburetter comprising a mixer casing having an air chamber and a mixing chamber, a mixing tube extending through the air chamber into the mixing chamber and provided with an air port opening into the former, fuel feeding means discharging into the mixing tube, an air valve arranged to constitute a diaphragm between the two chambers and provided with a sleeve member slidably mounted on the mixing tube, a spring held lever engaging the air valve and normally holding the same closed, and an adjustable regulator for said lever.

888,504. Wheel. Arthur L. Jimenez, New York, N. Y., assignor of 45-100 to William Freeman and 5-100 to Joseph Lopez Jimenez, New York, N. Y. Filed April 6, 1907. Serial No. 366,811.

1. The combination with spokes each having an annular shoulder between its ends and a rigid felly secured to the outer ends of said spokes, of a casing embracing the felly and the outer ends of the spokes, a tire carried by said casing and a cushion within the casing between the felly and tire.

888,523. Friction Clutch. Swinfen Bramley-Moore, London, Eigland. Filed Feb. 23, 1907. Serial No. 358,900.

1. The combination in a friction clutch of the single cone type, of a part fixed to the driving shaft, a movable part carried by a sleeve mounted to slide on the driven shaft, an intermediate piece located between the two parts of the clutch, a spring operating between the said intermediate piece and the movable part of the clutch, a second spring operating between the said intermediate piece and the part of the clutch carried by the driving axle, a stop carried by the movable part of the clutch, a sleeve carrying the intermediate piece, and a grooved collar carried by the said sliding sleeve, as set forth.

888,535. Motor Road Vehicle. Frederick H. Royce, Manchester, England. Filed Aug. 12, 1907. Serial No. 388,159.

1. Means for suspending the motor and gear box in the frame of a motor road vehicle comprising four arms projecting from each part the rear two of which are rigidly fixed to the frame, bell crank levers pivoted to the other two arms, the one end of each bell crank lever being connected to the frame, and a coupling rod connecting the other ends of said bell crank levers, as set forth.

888,589. Drive and Steering Gear for Automobile Vehicles. Edward P. Cooper, Paw Paw, Mich., assignor of one-half to Olin James Cooper, Hillsdale, Mich. Filed Feb. 25, 1907. Serial No. 359,083.

1. The combination of the front and rear frames; a swivel connection for said frames; hollow axles; hollow spindles for said axles; vertically arranged pivots for the connecting said spindles to said axles; tubular axle shafts arranged in said axles; spindle shafts arranged in said spindles; gears on said axles and spindle shafts; connecting gears for said axle and spindle shaft gears mounted on said spindle pivots; wheels mounted on said axle spindles and connected to said spindle shafts; steering shafts arranged in said axle shafts; gears on the outer ends of said steering shafts; gears secured to said spindle pivots and arranged to mesh with said gears on said steering

Digitized by Google

shafts; a pair of adjustably mounted plates curved in cross section having a pair of diagonally arranged grooves in their inner faces, said grooves diverging in each direction from a central point, each groove being substantially straight on one side of its central point and curved on the other; pins carried by said steering shafts arranged to engage the grooves in said plates; a steering rod; connecting cables for said steering rod to said plates whereby they are adjusted; guide pulleys for said cables, the guide pulleys for the front plate being arranged on the said front frame and those for the rear plate being arranged on the said rear frame; a driving shaft; gear connections therefor to a pair of the said axle shafts; transmission shafts arranged in pairs; gear connections for one of each pair or said transmission shafts to said driving shaft and for the other pair of said transmission shafts to the other pair of axle shafts; driving connections for said pairs of transmission shafts, consisting of wheels having rod-like spokes to said shafts, rim blocks slidably mounted on said spokes, discs having tangentially arranged grooves in their inner faces adapted to engage said blocks whereby, when said discs are adjusted, said blocks are shifted on said spokes, adjusting rods for said discs having spirally arranged grooves therein, and pins on said discs arranged to engage said grooves whereby, when said rods are shifted longitudinally, said discs are adjusted; connecting belts for said transmission wheels; connecting bars for said adjusting rods; and a connecting rod for said bars connected to said steering rod, all coacting for the purpose specified.

888,594. Transmission Mechanism. Orson W. Davis, Rochester, N. Y., assignor to Gearless Transmission Co., Rochester, N. Y., a Corporation of New York. Filed Aug. 10, 1907. Serial No. 387,974.

1. In a transmission mechanism, the combination of the motor and driven shafts journaled to rotate independently, a main driving gear fixed to the end of the motor shaft having a hub with extended ends, a pinion carrying frame spanning the ends of said shafts and having its ends loosely journaled in said frame and meshing with the teeth of said driving gear, means for transmitting motion from said pinions to the driven shaft to reverse the motion thereof, means for locking one end of said pinion frame to the driven shaft, and means for locking the other end of said frame to the motor shaft.

888,597. Sparking Circuit Controller for Explosion Engines. Willard E. Dow, Braintree, Mass. Filed Feb. 8, 1904. Serial No. 192,481.

1. A rotary interrupter, comprising a rotary device provided with a tripping projection, and a series of straight, leaf contact springs extending tangentially of the path of said tripping projection, an adjustable contact for each spring extending toward the middle of said spring on the side thereof opposite said rotary device, each spring being held rigidly at its outer end in free suspension in the plane of said tangency and being thin, light, non-weighted and uniform in thickness from its support to its extreme free end, the latter terminating substantially at said point of tangency with the path of said tripping projection, and being engaged at its free tip end by the tripping projection as the latter is revolved by said tripping device.

888,628. Tire Tightening Apparatus. George R. Macomber, Chicago, Ill. Filed Feb. 8, 1908. Serial No. 414,963.

A device for expanding fellies comprising a hollow shell which is angular in cross section and provided with longitudinal, angular flanges, the ends of which are inwardly turned forming guideways, the outer faces of said inwardly turned portions of the flanges having ratchet teeth, the inner edges of which are flush with the inner end of said flanges, a hollow standard angular in cross section and telescoping within the guideways of said shell, a shaft journaled upon said standard, pins mounted eccentrically thereon, dogs pivoted to said pins and adapted to engage said ratchet teeth, as set forth.

888,705. Speed Indicator. Edwin T. Greenfield, Kiamesha, N. Y. Filed June 22, 1907. Serial No. 380,210.

The combination of a controlling device comprising a two-part casing having bearings formed therein, a shaft journaled in said bearings, a gear on said shaft outside the casing for driving the same, a body pivotally mounted on said shaft, a collar loose on the shaft, a spring for positioning the collar, a link connecting the collar and body, and a lever pivoted on said casing and engaging the collar, said body, collar, spring, link and lever being within the casing, an indicating instrument having an index movable relatively to a scale, a flexible tubing having one end communicating with an opening in said casing and the other end connected to said indicating instrunment, and two wires extending through said tubing and connected at one end to said lever and at the other to said index, said wires

Warner Auto-Meter

GUARANTEED FOR ONE YEAR.

"Thirty Days' Free Trial"

When a manufacturer is willing to send his product to anyone, anywhere, for 30 days—with no deposit, no agreement to buy, no promise to do anything except give that product a fair trial—he must have more than ordinary confidence in his article. In order for him to have that confidence he must have a most extraordinary product.

That's what we do. We'll send an Auto-Meter to any automobile owner in the country—with no deposit, no agreement, no promise to do anything but put it on his car and give it a fair trial. It doesn't matter whether he has another make of speed indicator already on the car or not. Indeed, for the sake of comparison, we hope he has. We will abide by the decision—for he will always keep the indicator that tells the truth. We claim for the Auto-Meter that it is the only one of which "the dial never lies." We believe that the instrument itself is the most eloquent salesman we have —we're willing to let it do our talking. Send to-day—just tell us what make and model of car you have—size of tires, etc.,—and we will send you an Auto-Meter.

being arranged to turn said index in opposite directions, substantially as set forth.

888,750. Speed Changing and Reversing Gearing. William A. Salter, Cedar Point, Kan. Filed Feb. 12, 1907. Serial No. 356,983.

1. In a change speed transmission mechanism, the combination of a driving shaft, a tubular driven shaft sleeved thereon, a small pinion mounted on and rotating with the driving shaft, a larger gear connected with the driven shaft, a stepped gear connecting said pinion on the driving shaft and gear on the driven shaft and mounted to rotate about the axis of the driving shaft and also about an independent axis, a casing rotatable about the axes of the shafts and provided with an internal gear meshing with larger of the pinions of the stepped gear, means for preventing said casing from rotating, other means for preventing said stepped gear from rotating about the axis of the driving shaft, and means mounted upon and rotating with the driving shaft and adapted to engage with the casing in order to lock the same to said shaft.

888,782. Spark Plug. Eligha Bruden, San Francisco, Cal. Filed Feb. 10, 1908. Serial No. 415,018.

1. A spark plug having a wire holder of non-conducting material and having a rear shoulder, two wires there-through, having exposed points adjacent to each other, between which the spark can pass, one of said wires extending to the outer end of the holder, and the other wire extending to said shoulder and being there exposed, and a metallic sleeve for the holder in contact with said exposed end and provided with means for securing it in the wall of an explosion chamber.

888,711. Sparking Plug. Louis Kantroditz, New York, N. Y. Filed March 6, 1907. Serial No. 360,931.

1. In a sparking plug, the combination of an electrode, and insulation around the same having a fixed portion and a vibrating portion.

888,876. Variable Transmission Mechanism. Orson W. Davis, Rochester, N. Y., assignor to Gearless Transmission Co., Rochester, N. Y., a Corporation of New York. Filed July 22, 1907. Serial No. 385,014.

1. In a frictional transmission mechanism, the combination of the motor shaft, a friction wheel movable axially thereon and rotatable therewith, a driven shaft in alignment with the motor shaft, a friction disc movable thereon and rotatable therewith, opposed friction wheels having plane faces adapted to engage the periphery of the friction disc on the driven shaft, means for moving the friction wheel on the motor shaft into engagement with the peripheries of the opposed friction wheels, means for moving said opposed friction wheels into engagement with the periphery of the disc on the driven shaft, and means for sliding said disc across the faces of said opposed wheels.

Running A Car By Ear

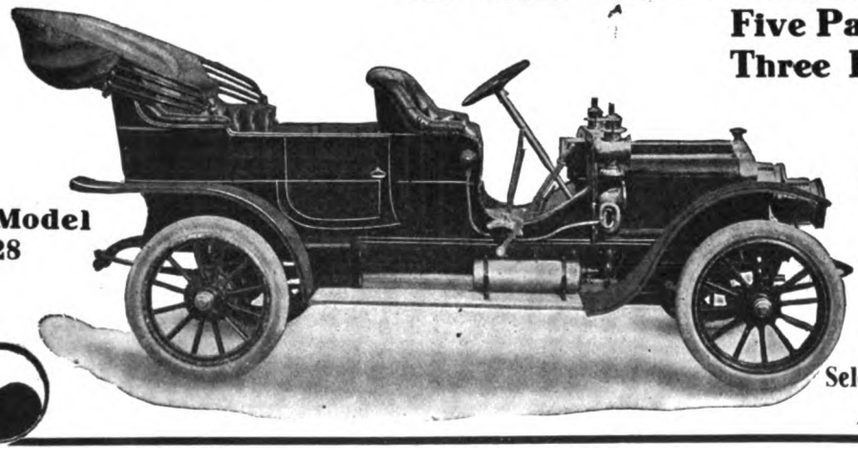
The trained ear of the experienced automobilist instantly detects the superiority of MOBILOIL in the even, contented "pur-r" of the engine that tells the story of perfect lubrication. No matter what the type of gasoline engine or season of the year, MOBILOIL invariably gives perfect lubrication under all conditions.

VACUUM

MOBILOIL

is made in five different grades, each grade meeting the particular requirements of certain automobiles.

A valuable booklet on motor lubrication will be sent free on application. Lists every automobile made, and shows grade of MOBILOIL necessary for its perfect lubrication. Contains track records and other useful information.



MOBILOIL in barrels, and in cans with patent pouring spout, is sold by all dealers.

Manufactured by

VACUUM OIL COMPANY, ROCHESTER, N. Y.

$2000

THE SELDEN CAR

Finished the Glidden Tour with a CLEAN SCORE and Was Deprived of a "Perfect Score" by a Technicality

We entered a stock car, which had already been run over 5,000 miles, without any shock absorbers, straps, bumpers or other safety appliances, complying strictly with the rules as to equipment. (All other cars were equipped with these devices.)

Our car was equipped with a speed indicator, the sprocket connection of which worked loose crossing the mountains in Western Pennsylvania and fouled our steering knuckle, making it impossible to avoid a large boulder in the middle of the road, and we broke a front spring in consequence.

The broken spring did not penalize us, nor the repairing of the spring, but because we used four machine-made nuts (instead of four hand-made nuts) we were disqualified from further contest for the Glidden Trophy.

Our car continued the tour as a non-contestant, checking in and out every day, observing all the rules and finished with a clean score.

It was in such good condition upon arriving at Saratoga that we made a non-stop run from Saratoga to Rochester, a distance of 272 miles on the following day without any adjustment whatever.

Our "extra parts" bag was not opened on the entire trip. No other car did any better.

COMPARE OUR CAR WITH OTHERS IN THE TOUR AND SEE WHAT WE HAVE ACCOMPLISHED

Demonstrating the highest quality of workmanship and material, durability, stability and the all-important fact that a strictly first-class gentlemen's car can be made and sold for $2000.

Why Pay Double the Price for a Name-Plate?

Duplicates of this car are now ready for delivery.

All our cars are sold with a guarantee and with all that we have out during the past season the cost of repairs amounts to little or nothing.

The "Silent Selden" (as the car has become known by its quiet running) is made on honor, a credit to the name of the man who invented gasolene automobiles, and every owner is proud of his purchase.

Superb riding, roomy tonneau, luxurious upholstery, smooth running, great hill climber, flexible and easily handled, economical in up-keep, stylish and attractive—the coming car of the multitude.

Now closing 1909 agencies—over half our output already spoken for. Good live agents wanted everywhere. Send for catalog and agency proposition.

THOMAS The World's Champion

The Thomas Flyer Wins the Race Around the World

The Thomas Flyer entered Paris Thursday, July 30th, winning the New York to Paris race, the greatest endurance contest in history, by TWENTY-SIX DAYS, and being the ONLY car of all those entered TO GO THE OFFICIAL ROUTE. The Thomas traveled 2385 miles on land under its own power MORE than its nearest competitor, and this over the worst, the most racking portions of the route, and under the worst conditions. In addition to this the Thomas traveled 3246 miles farther by water—a total of 5031 miles farther than its nearest competitor, which shipped by rail from Pocatello, Idaho, to Seattle, avoiding the most severe portion of the road across the American continent. That the Thomas should arrive in Paris only four days behind the German car, which traveled 5031 miles less, is sufficiently remarkable to cause world-wide comment. That the Thomas should perform this feat in spite of days lost by misdirection—in spite of days lost by the cornering of all the gasoline at Vladivostok by a foreign competitor—these facts and the fact that the Thomas which performed this feat is a regular stock car, are the reasons why all Europe is admitting today that America produces the best cars in the world, and that no car ever produced in any land can compare with the Thomas, or begin to duplicate its performance.

The Thomas Flyer which won the New York to Paris race was selected only six days before the race. It was already crated and tagged to be shipped to the Thomas agent in Boston. It was a stock model pure and simple and no change of any kind was made in any mechanical part, except the replacement of the drop front axle for one of the straight, such as are ordinarily used on Thomas cars shipped to Western districts. After traveling 13,431 miles over the worst roads ever attempted by any car, the Thomas is reported to be in excellent condition, and save for the physical exhaustion of its crew due to the terrific pace they made driving day and night through almost trackless wilderness COULD START FROM PARIS TODAY AND COME BACK OVER THE SAME ROUTE.

It is doubtful if American motorists will ever learn the whole of the frightful conditions the Thomas car met and successfully overcame. That of all the specially built foreign cars to start, one of them should actually finish directly contradicts the expressed opinions of many automobile experts, who frankly declared the route impassable to any self-propelled vehicle ever made. But that the Thomas, a simple stock car, should not only finish, but should be the only car to cover the official route, should win by TWENTY-SIX DAYS, defeating all these specially built foreign champions, proves that America is years ahead in the building of SERVICE cars, and that the Thomas leads the world in automobile construction by the same wide margin that the Thomas Flyer led all comers of all nations in the great race round the world.

The route of the racers led over the worst roads of the American continent at the worst time of year, through the heaviest snows of the winter, through the enormous snowdrifts, the heavy wind and deep ruts of Russia and Siberia in the rainy season, through almost impassable swamps, thousands of miles remote from civilization and repair shops, through unknown countries, over unknown and unbroken roads. A large proportion of this traveling was done at night, when road obstacles, avoidable in the day time, assumed the most dangerous proportions. Contrast this performance with the EASY DAYLIGHT TRAVEL OF A GLIDDEN TOUR ON WELL TRAVELED ROADS, ALWAYS AMIDST FRIENDS AND IN SIGHT OF VILLAGES OR FARMHOUSES, and the difference between the Thomas feat and the most trying public performances of other American cars will be readily apparent.

Every 1907-8 stock Thomas Flyer is a mechanical duplicate of this world's champion, and every 1908-9 Thomas Flyer is equal to this car in EVERY way, and superior to it in MANY ways, and ready at any moment for a trip 'round the world.

Large Sales

make it possible for us to import **THE CELEBRATED BRAMPTON CHAINS** from **ENGLAND** (paying freight and duty), and sell them at the same price at which the several other automobile chains are sold to manufacturers, jobbers, dealers and users.

THE BRAMPTON MOTOR CHAIN

All side plates on both sides on the Brampton Chain are stamped **"BRAMPTON."**

LARGE SALES and SMALL PROFIT with thousands of satisfied customers is our best advertisement.

THE BRAMPTON CHAIN is made of helf-hardening Steel; the strongest Chain in the World. All parts polished; fits sprockets (that are properly cut) without friction.

Some of the other chains may look like **THE CELEBRATED BRAMPTON CHAIN** because some of the other chain makers began to copy the design and shape of the **BRAMPTON CHAIN** links in 1904. They have improved somewhat on their copied design from time to time until these chains now look more like the **BRAMPTON CHAIN** than ever before. These chains somewhat resemble the **BRAMPTON** in appearance, but the manufacturers of such chains have been unable to copy the material—self-hardening steel.

NO CHANGE IN THE BRAMPTON

There has been no change in the design, construction, material or finish of the **BRAMPTON MOTOR CHAIN** in the past ten years.—**"ENUF SED."**

PRICE

The price being equal, it's presumable you want the best, and full value for your money. In such cases, the **BRAMPTON FILLS THE BILL,** and the prices are the same to manufacturers, jobbers, dealers and consumers as any other chain of equal size—as follows:

CHAINS TO FIT AMERICAN CARS

1 x ⅜ x 9-16—1 x ½ x ⅝—1 x ½ x 9-16 roller	$1.00 per foot.
1 x ⅝ x ⅝ roller	1.17 "
1¼ x ½ x ⅝—1¼ x ⅝ x ⅝—1¼ x ⅝ x ¾ roller	1.25 "

We also carry in stock the **BRAMPTON CHAINS** to fit Foreign Cars—Mercedes, Panhard, Martini, Fiat, etc.

Your 1908 Car

You can have the new car that you order fitted with the **CELEBRATED BRAMPTON CHAIN** if you order it that way. No extra cost to either you or the manufacturer. All standard sizes in stock to fit American and Foreign Cars at the same price as the other chains.

SPECIAL CHAINS TO FIT THE INDIAN MOTORCYCLE.

Agents wanted in unoccupied territory. Catalog on request.

We are Sole American Agents for **BRAMPTON CHAINS,** and they cannot be bought from anyone else except through our Agents.

Pan-American Automobile Body Polish

Pan-American Polish was awarded the Bronze Medal at the Louisiana Purchase Exposition at St. Louis, 1904. This polish has been carefully prepared for the Automobile trade. It is also applicable to the carriage trade, or can be used on any varnished furniture or woodwork of any kind. It will remove stains, cover scratches; leaves the automobile with its original new lustre, without being sticky or greasy. Furnished in eight-ounce bottles. Guaranteed not to harm the finest varnish. For sale by all Automobile Dealers. Price 60 cents per bottle.

The Miller Automobile Jack

The Miller Automobile Jack is a quick acting, automatic lowering jack, designed especially for automobile use, and is adapted to the factory or garage as well as to be carried as a part of the equipment on motor cars. It is high-grade and one of the finest finished jacks on the market. We guarantee this jack for twelve months. The list price of the Miller Jack, $3.50 each.

The Car You Can Afford to Buy and Keep

is the Mitchell.

—Because it is moderate in **price** ($1,000 to $2,800).

—Just as stylish, handsome and well finished as **any** car.

—And is perfect in each **detail** of construction.

—Doing just as well on the road and **standing up** to **wear** and **tear** just as well as the **extravagantly high-priced** cars.

Know this for **yourself**, Mr. Business Man.

Get **demonstrations** of the high-priced cars.

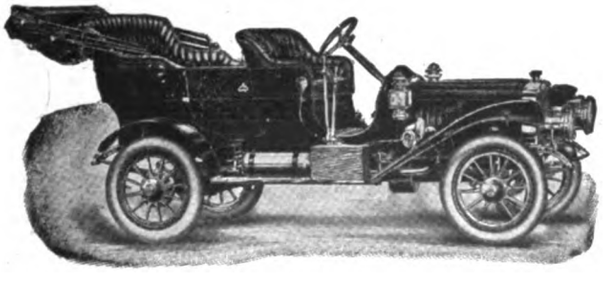
Then form **your** opinion in a demonstration of the **Mitchell.**

The Mitchell agent will be glad to take you out for 50 or 100 miles any day.

Call him up—you are placed under no obligation.

$2000

Just say "Show Me"



He'll answer with the **car**—show you a "**silent** argument" that will convince you.

Write for letters proving that the Mitchell is the most economical car to **operate**, and for catalog No. 18, picturing and describing the Mitchell Touring Car $2,000, Limousine $2,800, Roadster $1,250, and Runabout $1,000.

Touring Car shown here—5 passenger, 35 h. p., 4 cylinder, speed 50 miles, finished in Mitchell blue—a very neat and extremely desirable car from radiator to tail light.

Mitchell Motor Car Co., 285 Mitchell St., Racine, Wis.

Standard Manufacturers,
A. M. C. M. A.

Mongrel or Thoroughbred?

NOW IS THE TIME for you, Mr. Thoughtful Dealer, to decide what you will sell in 1909.

WILL IT BE A MONGREL? a car assembled from parts carried together from all over the country and hammered into shape as well as may be?

OR WILL YOU SELL THE THOROUGHBRED—a homogeneous mechanical masterpiece, every single part of which is the result of the same genius that devised the whole?

"ASTOUNDING," "MARVELOUS," "WONDERFUL," are the terms with which some assembled cars are now tagged, though they are astounding, marvelous and wonderful only to the assemblers, who like Rip Van Winkle, have been dozing in the growing woods of automobiledom and who now, bewildered by the progress that has been going on, seize upon time-tried and long-established practices and herald their adoption by the assemblers as brand-new discoveries.

LET'S REASON IT OUT: On the one hand you have the assembled car, with an engine bought from one manufacturer, a frame from another, and a transmission from a third, and so on down to the last rivet. The maker of the engine, the mill in which the frames are pressed, the transmission man, all derive their separate profits, leaving no other way to the assemblers to obtain their rewards than by skimping the quality of their "product."

AND THEY DO IT—THEY MUST! When you examine some of these astounding cars you will be truly astounded on finding that the four-cylinder engine is cast in one piece and has only two main bearings, whereas the Maxwell has four cylinders and five main bearings. You know well enough that making a motor with only two bearings is equal to leaving the engine to its own devices as far as alignment is concerned.

IT WILL BE A TOUGH JOB FOR THE DEALER to convince the purchaser who is wise that some four-cylinder engines of small dimensions will develop as high as 30 horsepower—because they can't.

MAXWELLS ARE A HOME-GROWN AMERICAN PRODUCT. The use of Maxwell features in Maxwell cars was neither a heaven-given inspiration nor the aping of foreign design, but the outcome of sound engineering sense.

WHEN 10,116 MAXWELL OWNERS testify to the excellence of their cars, all of which have been sold by Maxwell dealers, then the Maxwell proposition is one that you can't afford to pass by.

BEFORE HITCHING YOUR WAGON TO A STAR it will be wise for you to find out all about a dealership for Maxwells, the success of which is past and present, instead of lying in the dark and distant future that has swallowed so many wonderful cars that have been marvelous chiefly in their complete and rapid disappearance from the field of legitimate competition.

Benj. Briscoe
President.

WEED CHAINS

Made Perfect Scores Possible in the Glidden Tour

Had it not been for Weed Chains it is doubtful if any of the cars in the Glidden Tour would have completed the 1669.7 miles run with perfect scores.

Mrs. Cuneo's telegram shown above, makes clear that it would not have been possible to travel on the wet, slippery roads without the use of Weeds.

Weed Chains when attached to your tires positively prevent skidding. They grip and hold the wheels to the road, and enable the heaviest automobile to climb hills, or negotiate in mud or sand without any trouble. They prevent lost traction, and reduce gasolene consumption. Fit any standard tires; are readily attached and detached.

Write for "THE WEED," a Bulletin

"Firestone" Tires

"The Tires of Sterling Quality"

are different from other tires—distinctly different—decidedly better—their "betterness" lies in their durability and low mileage cost.

Equip one of your wheels with a Firestone tire—compare its quality and durability with the other tires.

We are confident the comparison will result in your equipping your car throughout with Firestone tires.

Branches and Agencies Almost Everywhere.

Firestone Tire & Rubber Co., Akron, Ohio

on a midwinter trip from New York to New Orleans, Mr. Ralph Owen driving an **Oldsmobile,** found in plenty, incidents and conditions of the sort that showed the kind of stuff men and things are made of.

When you stop to consider what an automobile is built and intended for, the endurance of this car is marvelous. He says:

"Between Blue Stores and Hudson the road was particularly rough and rutty, and as we were nearing Hudson one of our rear tires was wrenched off in a frozen rut which was nearly eight inches deep. At Buffalo, a thorough examination of the car was made to see if the terrible strain under which it had been the last three days had in any way decreased its efficiency, but aside from a broken spark plug, which had given us some annoyance the last ten miles into Buffalo, nothing was discovered."

This Car was equipped with TIMKEN ROLLER BEARINGS AND AXLES

Has it ever occurred to you WHY the manufacturers invariably equip the cars they pick for such trips, with **Timken Product?** There is a reason. May we give it to you?

Rambler

Model 34

Price, $2,250

TRY IT ON THE HILLS

Test this car at half speed on a hill or sand road where power and every ounce of it is needed. Notice how steadily and powerfully it pulls when running slowly under load.

The capacity of the offset crank shaft for doing this extra work is most noticeable at low engine speeds. All that power which in other engines is lost through friction on the bearings and cylinder walls, is added to the driving force by the Rambler offset crank shaft. It reduces friction; eliminates hammer and bearings; gives more power.

The straight line drive delivers the power direct and with least frictional loss to the rear axle. Let us demonstrate these features and the silence and the comfort of this car.

Tell our nearest representative to call at your home and take you to your place of business some morning in a Rambler. Or write your name and address and "Model 34" on a postal and mail to us today.

TIRE CONCERT OUT OF TUNE

Deadlock at Cleveland Meeting of the Makers—"Railroading" Methods Arouse Resentment.

Cleveland, O., Aug. 11.—Short, sharp and exciting was the session of the tire makers who gathered in Cleveland to-day to see what could be done about the plan of reducing tire cost to the consumer and of eliminating the price cutting evil. While all of the makers represented made it plain that they were in perfect sympathy with the proposed movement, the meeting itself ended in a deadlock brought about chiefly by actions on the part of the chairman which were regarded as an attempt to "railroad through" a resolution sweeping in its effects and which included clauses and conditions with which the members had not been given time to familiarize themselves. The form of the resolution, even more than its substance, was objected to, as was also the manner of its presentation with a flourish of the "big stick" and dire threats of what would happen to those who opposed it.

The effort to jam the resolution through, supplemented with a statement that both the Licensed and "unlicensed" automobile associations had pledged support, resulted in failure and defeat, despite the chairman's decree that he would make outcasts of the offenders who opposed him, by reporting their names to the automobile associations. The opposing members were incensed that the chairman should undertake to represent them as desiring to obstruct the wishes of the automobile manufacturers, when, as a matter of fact, they are in sympathy with some plan to reduce the evils of price cutting and are ready and willing to take united action, could a course be outlined that would be just to all.

The vote was a tie and the close of the meeting, which soon followed, found the manufacturers decided in going their separate ways, though indicating that they are in accord with the purposes for which the meeting was ostensibly called and will carry them out individually, without concerted action. On the question of reduced list prices all the makers were united, and action along this line is a foregone conclusion. Lessened discounts will naturally follow, though a perfectly uniform discount would seem out of the question. Representation by but one agent in a town and by none where a branch house is located created a difference of opinion and was the subject of sharp debate.

While the meetings in New York and Cleveland did not accomplish anything definite, benefits will follow in the reduction of list prices and the general improvement of trade conditions.

Takes Half of the E-M-F Output.

By an arrangement between the Everitt-Metzger-Flanders Co., of Detroit, and the Studebaker Automobile Co., of South Bend, Ind., the latter concern will undertake the marketing of half the proposed production of 12,000 E-M-F cars in the season of 1909. Studebaker outlets not only in the United States, but also abroad will be used, and as sold by the Studebaker agencies the price of the car will be $1,300 complete with touring equipment. The new arrangement does not affect the Studebaker relations with the Garford.

Logan Goes into Bankruptcy.

The Logan Construction Co., of Chillicothe, O., filed a petition in bankruptcy on Monday, August 11, showing liabilities of $120,000 and assets estimated at $69,000. The concern was organized with local capital a few years ago to devote itself chiefly to the commercial vehicle field. It was recently reorganized, but apparently without successful result.

Blomstrom to be Enlarged.

The Blomstrom Manufacturing Co., of Detroit, Mich., has increased its capital stock to $500,000. The increase is underwritten by Pittsburg capitalists. Extensive increases in the plant are contemplated.

LICENSED SESSION'S LIVELY

Buick President Scores the Members—Develops a Warm Answer—Standard Rim is Adopted.

Instead of the usually placid program, considerable heat was genrated at the general meeting of the Association of Licensed Automobile Manufacturers in New York, on August 7, by the fervid remarks of W. C. Durant, of the Buick Motor Co., who took occasion to score other members for alleged offenses of policy of which he did not approve.

He was particularly aroused by a letter which a short time ago emanated from the new Everitt-Metzger-Flanders combination in Detroit, and which, while being marked "Confidential," was extensively circulated in the trade. The letter was in the nature of a "wait-for-the-big-show" notice and incidentally made numerous and free remarks about other makers and "assembled" cars and took liberties with Durant's proposed International Motor Co. After paying his respects to the E-M-F letter, Durant turned to the Cadillac Motor Car Co., and accused it of disturbing trade conditions and of putting a heavy burden on agents with unsold cars by announcing and advertising a sensational new model so long a time in advance of its actual appearance or possible delivery. In conclusion he arraigned all the members of the association for alleged lack of co-operation and for not working together for the best interests of the industry.

When he had quite finished, Thomas Henderson, of the Winton Motor Carriage Co., undertook to call attention to the fact that it had been about two years since Durant or any of his representatives had manifested enough interest in the meetings of the association even to attend, thus suggesting the possible suspicion of the very lack of co-operation to which he took exception. The speaker further recalled that one of

Digitized by Google

the most conspicuous instances of advance notice work that the trade had ever seen was the heralding at the 1907 New York show, in January, of a light, four-cylinder, low priced Buick model for delivery some time after the following August.

H. H. Franklin, president of the H. H. Franklin Mfg Co., of Syracuse, resigned as treasurer of the association, a post he has held for the past three years. Colonel George Pope, treasurer of the Pope Mfg. Co., was unanimously elected to succeed him.

The report of the show committee was accepted, and it was decided that allotments of space at the Madison Square Garden show will be made at the next general meeting, which will probably be held early in September. It was recomended that the usual method of allotment be adopted, which is according to the amount of business done from July 1, 1907, to July 1, 1908. The decorative contract has been awarded to the S. R. Ball Co., as heretofore, and a new method of arranging the elevated platforms will give five thousand feet more floor space than in previous years. The report of the handbook comittee was also accepted, and work on the 1909 handbook will commence at once.

After discussing the new standard, universal quick detachable rim, the association approved the recommendations of its rim and tire committe, and adopted it as the standard for equipment.

Those present were: M. I. Brock, Autocar; W. C. Durant, Buick; W. C. Leland, Cadillac; R. D. Chapin, Chalmers-Detroit; M. S. Hart, Corbin; E. R. Hewitt, Hewitt; A. N. Mayo, Knox; S. T. Davis, Jr., Locomobile; V. M. Gunderson and W. E. Metzger, Northern; F. L. Smith, Olds; M. J. Budlong, Packard; L. H. Kittridge, Peerless; C. Clifton, Pierce; Geo. Pope, Pope; G. E. Mitchell, Alden Sampson; R. H. Salmons, Selden; F. B. Stearns, Stearns; I. H. Page, Stevens-Duryea. A. W. Church and O. G. Bechtel, Waltham; Thomas Henderson, Winton.

Stepney Agency to Dissolve.

A temporary receiver has been appointed by Justice Goff of the Supreme Court for the Stepney Spare Wheel Agency, of 341 Fifth avenue, New York City. An order to show why the corporation should not be dissolved was set down for September 28, following an application for voluntary dissolution by the directors, who allege it to be insolvent. The corporation has no direct connection with the Spare Motor Wheel of America, Ltd., at Chicago, the makers of the Stepney wheel.

Fatal Explosion at Auto Gas Plant.

An acetylene gas explosion on August 6, at the Auto Gas plant in Albany, N. Y., completely wrecked the building and in addition to blowing the right leg off John B. Harrison, the manager, killed John Malone and William Fort. Malone's body was found in the debris of the factory while Fort, who was across the street mowing his lawn, was crushed by a flying gas tank. Great damage was done to neighboring buildings, while the loss at the plant, which is operated in connection with the Avery Portable Lighting Co., of Milwaukee, was over $20,000.

The Week's Incorporations.

Aurora, Ill.—Sommer Motor Co., under Illinois laws, with $25,000 capital. Corporators—Willis H. Baker, L. A. Sommer, Harold F. White.

Richmond, Va.—Gordon Motor Car Co., under Virginia laws, with $5,000 to $25,000 capital; to conduct automobile transfer business. Corporators—J. O. Hayes, W. F. Gordon, E. D. Hotchkiss.

Camden, N. J.—Chalmers Detroit Motor Co. of Philadelphia, under New Jersey laws, with $25,000 capital; to manufacture automobiles, etc. Corporators—F. R. Hansell, W. F. Eidell, J. A. MacPeak.

Hempstead, L. I.—New York Auto Supply Co., under New York laws, with $12,000 capital. Corporators—Benjamin D. Underhill, New Canaan, Conn.; George H. Sprague, George T. Sprague, Hewlett, N.Y.

Brooklyn, N. Y.—Interborough Garage Co., under New York laws, with $20,000 capital. Corporators—John F. O'Donnell, Pierce W. Grace, 44 Court street; Thornton J. Theall, 215 Montague street, Brooklyn, N. Y.

Warren, O.—Hitchcock Motor Co., under Ohio laws, with $20,000 capital; to manufacture and repair automobiles. Corporators—J. A. Hitchcock, W. H. Creahen, Herbert E. Craig, T. M. Burton, S. E. Wannamaker.

New York City, N. Y.—Elite Motor Service Co., under New York laws, with $100,000 capital. Corporators—William H. Barnard, 54 Howard stret; Willis B. Troy, 262 West Seventieth street. Edmonds Putney, 2 Rector street, New York City, N. Y.

Passaic, N. J.—Foxhall-Wilson Co., The, under New Jersey laws, with $5,000 capital; to manufacture and sell bicycles, automobiles and hardware supplies, etc. Corporators—Thomas Foxhall, Clarence A. Wilson, George H. Dalrymple.

New York City, N. Y.—City Motor Service, under New York laws, with $50,000 capital. Corporators—George A. Melbourne, 500 West 122d street; H. C. Fuller, 2783 Broadway, New York City, N. Y.; M. A. Doyle, 16 Butler street, Brooklyn, N. Y.

Bristol Begins Getting Busy.

The Bristol Engineering Co., of Bristol, Conn., which is to make motor cabs for the American Taxameter Cab Co., has started operations, F. E. Moskovics having brought over a number of draughtsmen and others from Kingston, N. Y., and set them to work in the new factory building on North Main street. The chief work that will be done in Bristol at present will be assembling, but parts making will be taken up later.

The American Taxameter Cab Co. itself has completed its organization so that the list of officers is now as follows: T. H. McInnerney, president; L. H. French, vice-president; W. B. Hurlburt, treasurer, and C. R. Teaboldt, secretary. The name of Frank A. Merrall, of Acker, Merrall & Condit, New York, has been added to the directors' list.

Philadelphia's Show Plans.

Dates for Philadelphia's automobile show have been fixed upon as January 23 to 30, and an effort will be made to obtain the Academy of Music instead of the First Regiment Armory which has been used heretofore. The Philadelphia Automobile Trade Association held its meeting last week, and put the control of the show in the hands of a committee consisting of President J. A. Wister, of Gawthrop & Wister; W. F. Smith, manager of the Philadelphna Rambler branch; and E. H. Fitch, local manager of the Diamond Rubber Co. The active management will be in the hands of J. H. Beck, as in former years.

Trade Tickets at Palace Show.

Details of the Grand Central Palace show, which opens on New Year's eve, were the subject of meetings on the part of the show committee of the American Motor Car Manufacturers' Association last week. The main floor and part of the first gallery will be occupied by American and foreign pleasure vehicles, and the taxicab division will be on the first balcony along with the commercial vehicles and motorcycles. The accessory makers will be on the first and second galleries. A liberal trade ticket plan for exhibitors has been decided upon.

Babcock to Make a Buggy Type.

A buggy type of automobile will be a new Watertown (N. Y.) product in the near future, the H. H. Babcock Mfg. Co. having decided to enter the field. Gears and motors for the trade are also to be made in the new factory which is being built adjacent to the company's other buildings.

Gramm Starts His Own Concern.

B. A. Gramm and Fred Bisantz have severed their connection with the Logan Construction Co., of Chillicothe, O., to devote themselves to the Gramm-Logan Motor Co., which Gramm has formed. A factory in northern Ohio has been chosen and work will commence within a few days.

Will Produce Motor Car Parts.

The Jackson, Church & Wilcox Co., of Saginaw, Mich., which has for some time been engaged in the manufacture of iron and steel products, has decided to take up the manufacture of automobile parts. To this end it is erecting a large factory supplementing its present buildings.

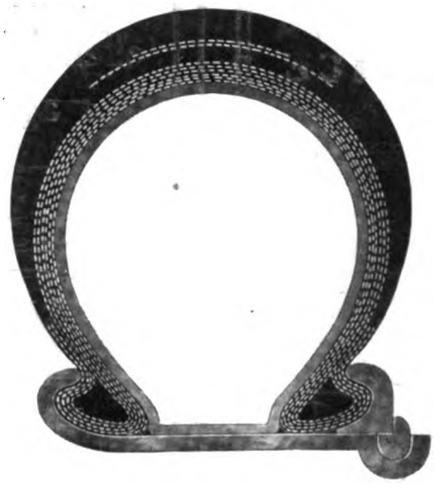
STANDARD RIM IS APPROVED

Experts from Associations of Car Makers Unite on a Design—Details of Construction.



After two years of delay and interruption, the project for a standard quick detachable rim for general adoption by American automobile makers has assumed definite and concrete form. A new rim, differing in detail from any of the rims now on the market has been evolved, and has met with the approval of special committees appointed to investigate the subject by the Association of Licensed Automobile Manufacturers, the National Association of Automobile Manufacturers, and the American Motor Car Manufacturers' Association.

Efforts were made about a year ago to have the makers agree on one form of rim, but were discouraged to some extent by President Cutler of the Licensed Association, who took the the position that his association could not bind its members to adopt any particular style, even if it were selected by all the special committees. Despite the rivalry of the various rim makers and tire concerns, these interests have all along expressed themselves as ready to cooperate for a standard rim when the car makers as a whole could themselves decide on one and would back their decision with equipment orders.

The Licensed Association, whose Mechanical Branch is largely responsible for the form of rim which is now offered as the standard, has accepted the report of its special rim committee, and will urge the adoption of the new rim on all its members. Other large makers will be reached through the American Motor Car Manufacturers Association and the National Association of Automobile Manufacturers, the lesser and unattached manufacturers being depended upon to come into line through trade expediency and example.

In general construction the rim adopted follows certain principles which already have been approved through direct service in other devices of the sort. The main section comprises the base or rim proper and the inner flange, which is permanent. The outer flange is formed by a removable flange or ring, which is reversible, while this, in turn, is held in place by means of a second and locking ring. The latter is broken at one point in its circumference, while a tongue formed on its lower side, is arranged to interlock with a recess in the rim, by which it is secured from rotating about the latter and from springing out of position.

Two points of absolute novelty are to be found in the arrangement. One is the formation of the removable ring in such a way that in either of its two possible positions it forms an exact counterpart of the opposite flange without any break in its continuity. The second is the use of a locking ring which, instead of being of uniformly oval section, is recessed by the formation of a right-angled groove in its upper and inner side, in such a way as to permit the side ring to overlap it. In this way the latter is provided with a very broad seating

STANDARD RIM AS USED FOR CLINCHER TIRES

on the rim, while the contrivance also assists in the retention of the locking ring.

The rim is universal in that it will accommodate any tire of standard dimensions of either the clincher or Dunlop types. As shown in the accompanying illustrations, the method of adaptation to these two constructions is made plain, as is the sectional shape of the rim itself and the removable

STANDARD RIM AS USED FOR DUNLOP TIRES

flange and locking rings. For the accommodation of the Dunlop type, it will be observed that the outer flange is merely reversed and replaced, while the hollow of the permannt inner flange is adapted by the use of a special rubber filler ring.

In either position the removable flange is equally secure, and its method of manipulation is the same, so that there is no difficulty in changing from one to the other.

GETS BIG ROYALTY PAYMENT

Electric Vehicle's Coffers are Swelled by Selden Settlements—Report of the Receivers.

The bank account of the Electric Vehicle Co., of Hartford, was materially increased in July, according to the report filed by Receivers Halsey M. Barrett and Henry W. Nuckols, by the payment of Selden royalties by members of the licensed association, the receipts from this source being $236,915.77. This figure in a general way indicates the amount of royalty paid by the licensed concerns for the period from October, 1907, to July, 1908.

As the royalty paid under the Selden patent is 1 per cent. gross of the value of the cars sold, less 20 per cent, for cash in 15 days, the business done from October to July by the members of the licensed association is approximately $24,000,000. The licensed association gets two-fifths of the amount paid to the Electric Vehicle Co., and a payment of $95,533.59 to the association on the Selden patent account is shown by the report. Of its remaining three-fifths, the company has to pay George B. Selden himself a share, and a July payment of $11,776.68 under this arrangement is recorded.

The receivers' report is as follows:

Sales.	
Charges on account and cash sales	$33,803.76
Purchases.	
On account	$5,836.96
Cash	148.47
	$5,985.43

Taxes	12,082.55
	$147,396.23
Cash receipts	$390,166.46
Cash disbursements	147,396.23
Balance on hand Aug. 1, '08	$242,770.23

Coey's Taxicabs Destroyed by Fire.

Over 50 automobiles and taxicabs were destroyed by fire Wednesday, 12th inst., at the garage of C. A. Coey & Co., 1710-1718 Indiana avenue, Chicago. Coey's insurance was $11,000, which was but a small part of the total loss.

THE INCOMPARABLE WHITE

THE CAR FOR SERVICE

"LEAST DUST"

That the White raises less dust than any other car was proven beyond question in the "Dust Competition" held last year by the Royal Automobile Club of England on the Brooklands race track. In fact, so far superior was the performance of the White to that of all gasolene cars that the "Dust Competition" to be held this year is "for gasolene cars only." It has been arranged, however, that, in order to establish a standard, the White shall make trials under the same conditions as the gasolene contestants. The first prize is to be awarded to that gasolene car which makes a performance nearest in merit to that of the White.

The Need of a Standard Rim.

With the placing in nomination of a new candidate for the long-sought standard quick detachable rim for general use, and evidence that it may receive the official sanction of the three great manufacturing organizations, renewed emphasis is placed upon the importance of arriving at some definite conclusion in the matter. Tire construction offers many perplexing questions for decision, but perhaps none of greater present importance than the question of attachment. The introduction of the several types of quick detachable rim in present use has proved one of the greatest blessings the user has yet received. But not until it be possible to recognize a truly universal rim will the blessing be complete.

Of all the vexed problems which have followed in the train of the automobile, the tire problem has proved the most difficult of solution. Its vital nature in the matter of the expense of car upkeep assumes greater significance as the other items of expense are reduced through improved methods of construction. Furthermore, as it serves to reduce time losses on the road as well as labor and inconvenience, the importance of the quick detachable type increases in equal ratio. The facts that by its use the number of tire failures due to improper manipulation is decreased and that less skill is required in handling it than in the use of the plain clincher type, also count tremendously in its favor.

That the adoption of a satisfactory universal method of construction, however desirable it may be, is not a simple matter, is in no way better evidenced than by the fact that the question has been under expert consideration for two years without any definite conclusion having been reached. Nor is the difficulty wholly one of the accommodation of a number of conflicting manufacturing interests. In the purely structural sense, the problem offers many obstacles which are not to be surmounted readily. Many of the otherwise effective solutions which present themselves are useless for the purpose because of the particularly arduous duty which is thrown upon the rim; its exposed location, the severe and varied stresses which it must resist, and the unavoidable presence of quantities of dirt, mud and grease. The truly successful rim must be a marvel of simplicity and security.

Once developed and introduced, however, there can be no question of the cordiality of its reception. Whatever may be the limit of advisable standardization in automobile construction, it is unquestionable that all tires should possess the virtue of absolute interchangeability.

Rural Free Delivery and Good Roads.

In the spread of the good roads movement the fact must not be lost sight of that the Rural Free Delivery of the mails may be made an effective weapon of advancement. Just as the carriage of the mails on railway trains has been made an important factor in the development of the fast schedule, the improved facilities for handling the farmer's budget of correspondence and his papers which the good road presents in conjunction with the free delivery route of the country may be turned to good account. The motor vehicle is coming to be of recognized importance to the rural letter carrier, and the amount of time which he is enabled to save by its use constitutes a virtual reduction of the distance between the farm and the town. Yet the efficacy of the motor vehicle depends to a great extent upon the condition of the highways over which it must be driven.

When the farmer learns that his own neglect of the highway problem must involve a break in the regularity of the postal service at certain seasons of the year, he is destined to be aroused to the value of overcoming the obstacles which interfere with it. Furthermore, the likelihood that in time, the post office department may come to regard neglect of the highways over which its routes are laid as interference with its business, should hold out additional inducements for the development of automobile mail service. It is difficult to conceive of any single line of progress more comprehensive in its effects that that of the rural free delivery. And where its application may be made to affect the automobile industry as well as the automobilist in so general a way, no pains should be spared to work for its further spread.

Value of the Production Engineer.

In the light of the rapidly increasing movement for multiple production in the industry, the importance of the production engineer is rapidly becoming augmented to a point of absolute supremacy in the manufacturing department. Both in the matter of parts and complete machines, facility and economy of production are receiving constantly increasing valuation. The very design of the machine is made to a degree, subject to the ease with which it lends itself to the tools of the builder, and just as the construction of the special tools required for any of the modern processes forms one of the most vital elements of the process, so the man who is capable of originating those processes and tools is granted a mark of consideration to which he is justly entitled.

The peculiar aptitude which enables him to see in any given finished part not an element in a complex machine, but a problem to be solved—the product of a number of possible methods of evolution from the raw—and the nice discrimination which enables him to choose from several such methods the most economical and satisfactory one, are gifts developed by long training and special qualifications, which enable the true production engineer to assume a position of command and earn the high regard which is his justly earned reward.

Digitized by Google

In the automobile field is manifest a growing tendency to recognize the importance of this office and to depend upon its services. In many instances the task of laying out the work of production is not relegated to any one man, but is evolved in consultation. In others, it falls upon the shoulders of an overworked superintendent and receives only such attention as he can spare for it. It is a mark of growing industrial efficiency, however, that the number of plants which are being worked upon a more liberal basis is increasing rapidly.

That some of them are attracting men from outside the confines of the industry itself—men whose training has been entirely in lines where rapid and accurate work on a large scale has become a specialty, but adds another point to the argument that the business of making and selling automobiles is fast assuming well regulated proportions and that it presents a constantly broadening field for skilled engineering talent.

Again it appears that the only satisfactory solution of the touring contest problem rests in the adoption of automatic, mechanical observers. The recording speed ometer-odometer, or some device of its class, would record the speeds and running times of the cars with mathematical precision. The calculation of results, decisions as to questions of technicality, and all protests, would be left to the discretion of the judges. The human element of the ignorant or erring individual nominated by the contestants to fill a necessary place in the program and carry on duties of a doubtfully welcome character would be avoided, and the tourist and his party would be left to themselves. Why this idea has received no more than casual attention hitherto, is difficult to conceive.

A point of advantage of automobile travel over that which may be accomplished by railroad is that where the train follows its iron trail through winding valleys and under the hills, the automobile overtops it, and follows the sky-line. The better view, the better air and the spirit of freedom and conquest are thus a potent factor of enjoyment to the tourist who uses the modern method of transportation. That he may secure these advantages at wonderfully low cost, all things considered, and with no material sacrifice of bodily comfort, but adds to the pleasures of the tour.

CHICAGO AND M. A. M. MEMBERS

Show Situation Worries Accessory Men Who Want to Exhibit—N. A. A. M. Will Not Yield.

Considerable trade speculation has been set astir as to where the Motor and Accessory Manufacturers, Inc., is going to find itself as a result of the action of that part of its membership which gathered at Atlantic City, in taking the position that the whole association must refuse to exhibit at the Chicago show unless further special price concessions are made on space. Since a great part of the membership of the M. A. M. is drawn from firms who belong for practically no other reason than to get advantageous show space through the brokerage of the association, not a little uneasiness has been created among them as to how they are going to get out of the difficulty in which they have been placed so far as exhibiting at the National Association of Automobile Manufacturers' show in the Windy City is concerned. As the latter association has already made it plain that it will not reduce the price of space, the members of the accessory association must either stay out of the show or brave the possibility of not being permitted to exhibit in the M. A. M. space allotment at the New York shows.

Several of the larger members of the association are already devising methods for circumventing the full effects of the situation, arranging a plan by which their products will be well represented at Chicago without imperiling their rights to M. A. M. space at the New York show. Others, who are not satisfied at having to resort to measures of this kind, give intimations of revolt against the action at Atlantic City and some very frank expressions of opinion are being given. One prominent maker of accessories expresses great surprise that the association should antagonize the automobile manufacturers by demands for further concessions, particularly as the price of space at Chicago is lower than at the New York shows.

"At the Madison Square Garden show," he said, "we pay from $1.55 to $1.75 a square foot, participating in whatever dividends are declared, on the same basis as the Licensed car exhibitors, while at the N. A. A. M. show in Chicago we pay only 90 cents a foot, with 15 cents rebate to our association. As the Chicago show is the biggest of the lot, and will probably have more visitors than any of the other shows by reason of the fact that fully 60 per cent. of all the automobile business of the country has been done in the Middle West this year, there are a great many of us who feel that we want to show there if anywhere and are perfectly willing to pay the price. As things stand now, the M. A. M. would prohibit our exhibiting there under penalty of disbarment from M. A. M. space at the other shows, and we are decidedly up against it.

"To have a traveling salesman like Fred Castle introduce a resolution that binds us all against showing at Chicago unless the M. A. M. gets a bigger divide with the automobile makers seems bordering on presumption, as there is a whole lot of doubt as to how far such a traveling salesman can be thought to represent the wishes or disposition of the manufacturers in the association, not even excepting the firm he works for."

That the automobile makers are in no mood to knuckle to the demands of the accessory association is very evident from the terms in which members of the N. A. A. M. show and executive committees discuss the ultimatum which the M. A. M. has chosen to make.

"These accessory makers had their case passed upon long before they go up their unofficial ultimatum," said an automobile manufacturer who is a chief in the N. A. A. M. councils. "At a meeting some time back, we discussed the status of the accessory exhibitors and decided emphatically at that time that they were entitled to no more concessions than they had already received. In fact many of the automobile manufacturers thought we were treating them altogether too liberally. If they attempt to interfere with the success of our show at Chicago, it will have no harmful effect on us, as the space can readily be sold at much more profitable figures."

COMING EVENTS

August 14, Algonquin, Ill.—Chicago Motor Club's third annual hill climb.

August 15, Rochester, N. Y.—Rochester Automobile Club's annual gymkhana contest at Genesee Valley Park.

Sept. 1, 2, 3, and 4, Chicago, Ill.—Chicago Motor Club's postponed 1,000-mile reliability run.

September 5-9, Los Angeles, Cal.—Automobile Dealers Association's reliability run to San Francisco.

Sept. 7, Columbus, Ohio.—Columbus Automobile Club's race meet.

September 7, Lowell, Mass.—Lowell Automobile Club's 200 miles road race, on Merrimac Valley boulevard.

September 7, Columbus, Ohio.—Columbus Automobile Club's race meet.

September 7-12, Hartford, Conn.—Connecticut State Fair Association's outdoor show and grand circuit races at Charter Oak Park.

September 11, Springfield, Mass.—Springfield Automobile Club's hill climb on Wilbraham hill.

DEMOUNTABLE RIMS IN A CONTEST

Diamond Wins in Practical Competitive Test at Chicago—Five Contestants Meet Strenuous Conditions.

Five cars, equipped with four varieties of demountable rim, took part in the "demountable rim contest" of the Chicago Motor Club on Thursday last, 6th inst. The first event of the sort to be held, it furnished an unusually happy method of comparing the respective merits of the devices under test.

First prize was awarded to the Diamond rim, its time of 5:36⅗ being composed of the added time for three changes, corrected by the addition of 24⅗ seconds penalization. Other rims tested in this way were the Continental, which was awarded second place, the Fisk and the Nadall.

The rules of the contest provided for four tire changes during the race, each of the four tires being shifted under the eye of an official observer, at different points along the famous Elgin-Aurora century course. When this test was completed, each car was required to make a special road test of the rims. Slipping and loosened bolts or nuts were taken note of and time penalties added for readjustments.

Five entrants participated. These were Diamond on an Isotta car, Fisk on a Chalmers-Detroit, Fisk on a Knox, Continental on a Packard, and Nadall on a Pierce Arrow. Comparisons at the finish showed that there was less than two minutes difference between contestants in time required for changes.

The Isotta, fitted with the winning Diamond tires, made a bad start, and lost its way on a wrong road soon after leaving Chicago. After cruising about for three or four hours, it finally rejoined the others at Elgin, long after the latter had finished. When the official examination was completed, however, this car, with its crew composed of William Kissner and George Brewer, proved to be the winner, despite ts tantaliiing experience.

The Continentals on the Packard were penalized 32 seconds due to loose nuts, while the Fisk entries came next. The latter, while getting only third place at best, won considerable glory by grabbing off the fastest single change made by any one of the contestants, dismounting and mounting a new rim in 53⅕ seconds at Ontarioville, while at Elgin the other Fisk entry recorded 54 seconds.

The Nadall demountable is a newcomer in the field and embodies some exceptional features, its particular advantage lying in the fact that there are absolutely no parts to lose and that the change can practically be made in the dark.

Diamond Demountable Rim—Isotta Fraschini car, George A. Brewer driver. Time, 1:01⅗, 1:25⅗, 1:45, 0:59⅗, penalty 0:24. Total, 5:36⅗.

Continental Demountable Rim—Packard roadster, Jack Hessler driver. Time, 1:02, 1:58⅕, 1:05⅗, 1:10⅗; penalty 0:32. Total, 5:48.

Fisk Demountable Rim—Knox roadster, H. W. Crane driver. Time, 1:07⅕, 0:57!, 5:53⅕, 5:58⅘; penalty, 1:53⅕. Total, 5:59⅘.

Fisk Demountable Rim—Chalmers-Detroit roadster; W. F. McCarthy driver. Time, 1.11⅗, 0:57, 1:01⅕, 0:54; penalty, 3:06⅗. Total, 7:10⅕.

Nadall Demountable Rim—Pierce; Paul Hoffman driver. Time, 2:02⅗, 1:17!, 1:25⅘, 1:29⅘; penalty, 1:20⅘. Total, 7:35⅘.

Planning Welcome for Thomas Crew.

Suitable demonstrations of joy and welcome are to be given George Shuster and George Miller, the triumphant drivers of the New York-Paris Thomas car, when they and the machine arrive in New York. They will come on the Lorraine and are due about August 18. The Harry S. Houpt Co., New York agents for the Thomas, will conduct an elaborate jollification, and Thomas car owners from all over the East will participate in the festivities. Delegations from the E. R. Thomas factory at Buffalo will also be present, and parades and other "doings" will arouse the public to "see who's here."

Because Diamond tires were used on the Thomas throughout its journey, the Diamond Rubber Co. feels its proportionate share in the victory, special commendation of the service the tires rendered having been given publicly by the Thomas people.

Lee Speediest on Chapel Hill.

Five events constituted the program of the hill climb on Chapel hill, New London, Conn., on the 1st inst. Incidentally the occasion afforded an opportunity for Corbin cars to come very close to making a clean sweep. That the opportunity was seized is shown by the results of the meet, for four events were won by this one make of car, which was not represented in the one other number on the program—the Class A event for cars selling for less that $1,200. In the free for all a new record for the hill was established by Arthur S. Lee, who drove a 30 Corbin, owned by H. B. Kenyon, of Eastern Point, up the incline in 1:12⅘, clipping ⅕ second from the former record.

Torrington Motorists Form Organization.

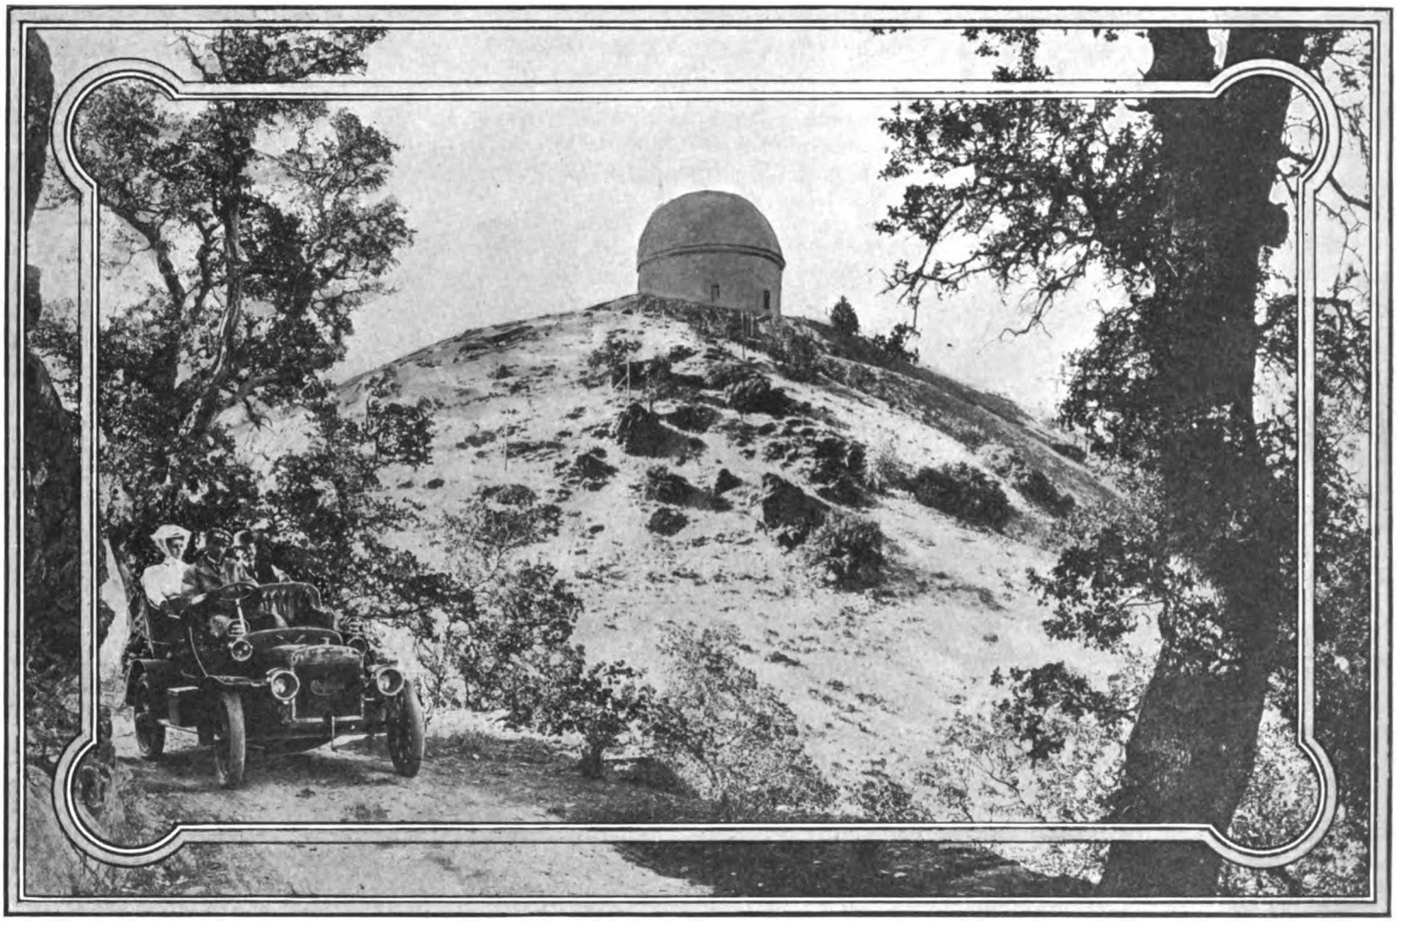
Motorists of Torrington, Conn., and vicinity have organized under the name of the Litchfield County Automobile Club. The following officers have been elected: President, N. D. Holbrook; vice-president, John N. Brooks; secretary, W. P. Norton, Jr.; treasurer, G. E. Cole. The club will join the Connecticut Automobile Association, and through that organization will be affiliated with the American Automobile Association.

STIFF COURSE FOR A CLIMBFEST

Wilbraham Hill Selected for Springfield Meet on September 11—Good Roadway but Very Heavy Grades.

One of the most severe tests ever offered to automobiles is now being prepared by the automobile club of Springfield, Mass., which became especially prominent in automobile circles through its being the first city to have a good roads convention and which is one of the livest automobile cities in the country. This test is to be a hill climb on Wilbraham hill, September 11. The course that is now being prepared will be one mile long and almost straightaway, without any of the dangerous curves that have marked other hill climbing courses, such as Giant's Despair in Wilkes Barre, Pa., or Dead Horse hill in Worcester.

The main features of this course will be the grades which will range from 8 to 22 per cent. The length of the hill is 5,280 feet, with a rise of 451.1 feet. The steepest grade is 22.1 per cent. and the average grade 8.58 per cent. Just before striking the 2,640 foot mark, the cars will get a down grade of 2 per cent., which will help them gather headway for the steepest part of the hill.



Originally, there was a wicked turn in the hill which, if left, would have made the climb prohibitive, but this turn is being bridged and other repairs are being made on the hill by the local club and when finished, the course will be as straight as the proverbial straight and narrow path. However this regularity of course and smoothness of roadbed which the club will make a feature of the course does not in any measure reduce the difficulty of the proposed climb.

The club has received from the American Automobile Association the necessary sanction, and since that time the committee in charge has been hard at work perfecting the plans. Although the list of events and prizes has not been prepared as yet, President Mark Aitken, of the club and one of the prime movers in the proposed climb, has announced that he will offer a handsome silver cup to be known as the President's cup, for the fastest time made on the hill, regardless of the event. This offer will enable some fast car to win two prizes instead of one and to also have the honor of making a record on Wilbraham mountain, which honor will be well worth winning without the cup.

As an ideal spot for an automobile contest, Wilbraham mountain probably has no equal. Within easy access from the city proper, it has a most picturesque location. There is ample room for cars of the contestants, visitors and the gathering of spectators on foot that always turn out for such an event. Several years ago this club held an automobile hill climb and the experience

AUTOMOBILE STAGE LINE TO A MOUNTAIN TOP

Climbing steep mountains with the motor car is getting to be child's play. This was demonstrated on the last two Glidden tours and the question now is: "Where will the automobile go next?" It would seem that there is no limit or restriction to its possibilities. Nature may have erected a sign, "No Admittance," in places for a time, but the American tourist with his American car does not believe in "signs." The canyons and heights of the Golden West that the short-story fine-writers glory over in the popular magazines, no longer hold any great terrors for the motorist.

Thousands of tourists who annually visit California, have a great desire to ascend Mt. Hamilton and see the sights at the world-famed Lick Observatory. It has always meant an exceedingly long tedious trip as no ordinary locomotive could make the climb. Heretofore a stage has been the common method by which tourists reached the top, but John H. McGehee, of Letcher's garage, San Jose, Cal., an aggressive motorist, calculated that an automobile stage would be the thing. He investigated at considerable length to find a car which was capable of doing the work. The friction driven Cartercar was finally selected to tackle the stiff task in which constant "climbing" and "braking" is required. The car is doing the business.

The accompanying picture shows it at its daily work. The road has an elevation of 2,100 feet in a distance of seven miles, and passengers riding at this altitude "can count the freckles on the face of the man in the moon," according to the facial specialists out that way. Anyhow, it is a good pull for an automobile. The view was made only recently, but the perpetual snow will be noticed upon the ground and shrubbery.

---

gained in conducting that affair has aided materially in the arrangement of this, so that there is every promise that the climb will be successful.

The committee in charge of the climb comprises the following members. Mark Aitken, Arthur A. Adams, Albert E. Lerche, J. Walter Norcross and Merrill T. White.

Chicago Fails to Get Sanction.

That the American Automobile Association does not wish anything to detract from the interest in the Vanderbilt Cup, is evidenced by its failure as yet to grant a sanction to the Chicago Automobile Club to hold the contest for the Jefferson de Mont Thompson cup over the Indiana course in the fall. With Savannah competing with the Vanderbilt for prestige, the Three A's evidently feel that one big road race under its own auspices is sufficient for the rest of this year. That such a project would be better received in connection with an early 1909 date, is to be inferred.

When the office of the association was consulted for information on this subject Wednesday, a non-committal reply was received. The latest issue of the Journal of the Chicago Automobile Club comments on the matter in a manner that indicates that the question is not settled. It says:

"Plans of the Chicago Automobile Club racing board for a speed classic over an Indiana circuit next fall have come into sharp collision with the Vanderbilt race. The outcome is at present uncertain."

Muskegon Holding Floral Parade.

"Old home week" in Muskegon, Mich., which now is being celebrated, is to be the occasion of a big automobile floral parade which will take place to-day (Thursday). About 2,500 former residents of the city have returned to their native place and arrangements for their entertainment have been elaborated.

The Auto Club of France finds that receipts for this year's grand prix competition at Dieppe totalled $100,000. The expenditures were $72,000.

CURTAIN RAISER FOR SAVANNAH

Race for Light Cars to Precede the "Outlaw" Grand Prize Event—Two Hundred Miles the Distance.

Plans have been prepared by the contest committee of the Automobile Club of America for a 200 miles race for light cars, to be run in connection with the Grand Prize race to be held at Savannah on Thanksgiving Day. This will be patterned after the Voiturette race held on the Dieppe circuit in France, on the day preceding the recent Grand Prix contest there. It will be held over a 10 miles parallelogram circuit, running for the greater part over a section of the main 28-mile course.

Henry Souther, chairman of the Technical Committee, has announced the conditions for the event, which will be held a day or two, or perhaps a week, before the 400 miles contest for racing machines. All entries must have a minimum weight of 850 pounds and 3¼ inches has been fixed as the maximum bore for four cylinder motors. For motors of other types an equivalent effective maximum area has been fixed in accordance with the following table, which allows for motors of from one to eight cylinders:

For Four Cycle Motors.	in.	mm. of bore
For one cylinder	7.50	190.8
For two cylinders	5.30	135.1
For three cylinders....	4.33	110.1
For four cylinders	3.75	95.4
For six cylinders	3.66	77.7
For eight cylinders	2.65	67.4
For Two Cycle Motors.		
For one cylinder	6.35	160.0
For two cylinders 4.50		114.0
For three cylinders	3.65	92.0
For four cylinders	3.18	81.0
For six cylinders	2.58	65.0
For eight cylinders....	2.24	56.0

The 850 pounds weight limit was arrived at by the Technical Committee, after a thorough investigation of the various light cars now on the market and this weight of entrants will be considered in the same manner as large cars; that is, stripped for racing trim.

The purpose of the proposed event is the laudable one of encouraging the development of small four and two-cylinder cars and also two-cycle engines. Many manufacturers are now building these small machines, it is explained, and would enter into contests more freely if the performances of the lighter product could be shown to advantage and not snowed under by the more exciting and sensational exhibitions of larger, higher powered cars.

To encourage entries it is announced that tryouts will not be confined to one or two hours in the early morning, as is the case on Long Island. But beginning October 1st, the course will be patrolled and placed at the disposal of candidates for four hours each day. According to the publicity bureau of the A. C. A. enough American entries are expected to warrant holding an elimination race for the Grand Prize candidates, as the latter "big" event is limited to 25 cars.

Outside the confines of the club, however, it is believed there is no need to worry on that score, as it is questioned whether the entry list of domestic cars will swell to any such extent. Due in a large measure to the fact that the Savannah meet is to be held in opposition to and without the sanction of the A. A. A., iti s expected the entries will be considerably restricted.

Gymkhana Scheduled at Rochester.

Plans have been completed by the Rochester (N. Y.) Automobile Club for the annual gymkhana which is to be held on Saturday next, 15th inst., at Genessee Valley Park. Twelve events will constitute the program, and as usual, considerable novelty will be injected into the affair.

In the 100 yards dash the contestants will drive with the wheels running on narrow strips of wood. The driver going the longest distance without leaving the track in the fastest time will be declared the winner. In the "hospital contest" a dummy will be thrown in front of a car moving at the rate of 15 miles an hour. Each car will carry a passenger, who must get out of the machine pick up the "injured" and return with him to the car which then will be driven to the "hospital" at the end of the line. The car accomplishing this feat in the least time will be declared the winner.

Dates for Chicago Reliability Run.

Definite dates have been set for the 1,000 miles reliability run of the Chicago Motor Club who have named October 6th, 7th, 8th and 9th, as the days of the contest. Originally the intention was to run the event in September, but fear of the equinoctial storms caused the latter days to be selected. Another reason which prompted the selection of these dates was the fact of the roads in that section of the country being at their best in October. Eight entries for this event already have been received and it is expected that last year's entries, which numbered 35, will be exceeded. The club will hold its third annual hill climb at Algonquin on Friday, 14th inst.

Registration Figures from Illinois.

Statistics compiled in the office of the Secretary of State of Illinois show that more than 15,000 automobiles now are registered in that State. Of this number, the month of July showed 920 new registrations, while June brought 918 into the list. The statistics show also that 118 different makes of cars were sold in the State during July.

There now are eight taximeter cab companies operating in London. The average day's income from each is about $11.20.

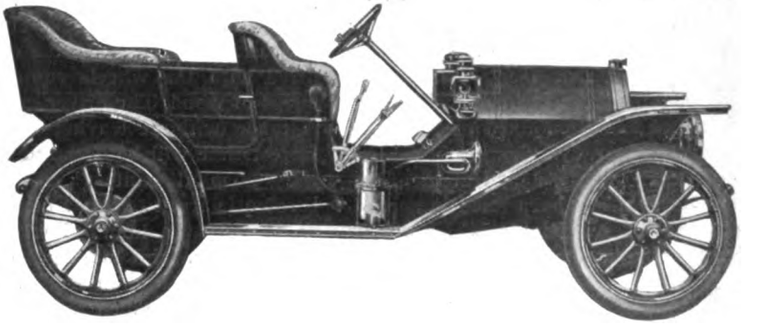
PURELY A TOUR OF THE TOURISTS

Only One Make of Car in Long Trip from Los Angeles—Reliability Test and Pleasuring Combined.

What is in many respects one of the most unique tours of the year started Wednesday from Los Angeles, Cal., under the auspices of the Auto Vehicle Co. of that city, the makers of the Tourist cars. It is purely a Tourist run and besides affording a measure of diversion for the entrants, it serves the purpose of demonstrating the strength of a purely local concern, which, from a comparatively modest beginning, has developed considerable strength on the Pacific coast.

The "tour of the Tourists," as the promoting company designates the reliability run, will be over a course slightly more than 1,000 miles in length and will consume 11 days. The longest day's ride will be 162 miles, and the shortest 55 miles, from San Jose to San Francisco. The itinerary provides for a two days' stop in San Francisco, and one day in Del Monte, where a special program has been arranged for the entertainment of the entrants.

The itinerary and time table of the run is the most complete thing of its kind that has been produced. It is a double page folder much in the form of a ledger sheet, the divisions on the pages provide space for printing the schedule running time from point to point, the distance between places, the total miles from the starting point; and the schedule of the pilot car. A wide column is devoted to "remarks," and under that head are printed brief comments calling attention to the historical incidents connected with the location, warnings of grade and crossings, road information and comments on the strictness with which local road laws are enforced. Gasolene stations are designated, and the folder contains other information of use to the tourists. Accompanying the folder is a booklet giving an epitome of the laws governing the operation of automobiles in the State and the regulations in force in the cities of Los Angeles and San Francisco.



In addition to the usual complement of officials, doctors, committees, etc., who are to be found with many runs of this nature, the tour is unique in that it has as a part of its makeup an "official" mixed quartet, and their accompanist. There is an entertainment committee to provide amusement for the travelers and an historian to make record of the events, that future generations may learn of the glories and accomplishments of the "first annual tour of the Tourists." The affair is planned, not as an endurance trial for men, but on a time schedule which should easily be adhered by a touring car with a full load, traveling solely for pleasure.

1909

Overland

Tourist

Model 32 — $1,500.00

SPECIFICATIONS

4-cylinder vertical motor, cast singly.
Bore 4, stroke 4½.
H. P., 30.
Lubrication — Mechanical oiler. Positive driven.
3 point suspension.
Water cooled, Thermo syphon.
Spark and throttle control on top of steering pillar.
Double system of ignition with high tension magneto.
Three speed selective transmission on rear axle.
Shaft drive bevel gear.
Internal expanding and external contracting brakes on hubs.
Wheels 34x3½ in. Artillery type.
Goodyear Q. D. Rims.
Water capacity, 5 gallons.
Gasoline, 12 gallons.
Weight, 1,900 lbs.
Wheel base, 110 in.
Tread, 56 in.
41 in. half elliptic front springs.
Full elliptic rear springs with involute ends.
"I" beam front axle.

The model 32 will undoubtedly prove the sensation of a sensational year. This car is in every way equal to machines which have hitherto sold in the neighborhood of $3,000. Only the very best of material is employed and the design of the car is beyond criticism.

A three-speed selective transmission will be used on this car, but it must not be taken from this that the planetary transmission used on our model 30 has not proven satisfactory—distinctly the reverse; but our representatives have urged upon us the necessity of building both types in order to enable them to cater to every class of purchasers, and we have fallen in with their wishes, thus making the Overland line the most complete on the market.

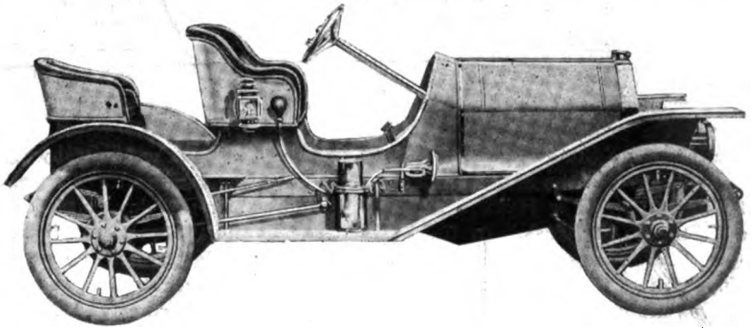
We would particularly draw attention to the fact that our cars are fully equipped for touring purposes, with the single exception of tops, and at $1,500 the model 32 Overland will be without a peer.

Model 34 — 6-Cylinder

We shall put on the market in September a six-cylinder car with 116" wheel base. The list price of this car has not yet been definitely decided, but it will not be over $2,000. This car has been designed to enable our representatives to take care of six-cylinder purchasers.

Watch for our announcement regarding this car, which will be made in the course of the next fourteen days.

OVERLAND AUTOMOBILE COMPANY



INDIANAPOLIS, INDIANA

1909

Overland

Roadster

Model 30—$1,250.00

SPECIFICATIONS

4-cylinder vertical motor, cast singly.
Bore 4, stroke 4½.
H. P., 30.
Lubrication — Mechanical oiler, Positive driven by eccentric.
3 point suspension.
Water cooled, Thermo syphon.
Spark throttle control on top of steering pillar.
Double system of ignition.
High tension magneto, gear driven.
Planetary transmission running in oil bath.
2 speeds forward and reverse, controlled by two foot pedals.
Shaft drive bevel gear.
Internal expanding hub brakes.
Wheel 32x3½ in., Artillery type, 1¼ in. spokes.
Goodyear Q. D. Rims.
Wheel base, 105 in.
Weight, 1,600 lbs.
Tread, 56 in.
"I" beam drop forge front axle.
5 lamps, generator and horn.
41 in. half elliptic front springs.
Full elliptic rear springs, involute ends.

The model 30 is the natural development of the Overland Roadster model 24, which has been so extraordinarily successful during the present season. The car has been enlarged in every way, but its salient features have been retained, notably the pedal controlled planetary transmission. The H. P. has been increased from 22 to 30, the wheel base from 96" to 105", the tire equipment from 32"x3" to 32"x3½", a high tension magneto added to the ignition system, and headlights and generator included in the regular equipment.

Semi-elliptic springs have been substituted for the full elliptic in front, and an "I" beam axle for the tubular used this year. The engine is the counterpart of that used in model 24, excepting that the bore has been increased to 4" from 3½". The body is exceedingly handsome in design, giving easy access to the rumble seat.

We are convinced that the Overland Roadster model 30 will be even more successful than its predecessor, and this is saying a great deal, for no car has leaped into public favor with such astonishing swiftness as the Overland.

Our factory accommodation is being trebled, and we shall be in first-class shape to take care of early deliveries. We have already closed many 1909 contracts and applications from unallotted territory should be forwarded immediately.

GOOD CLIMBING AT SALT LAKE

Ten Well Contested Events on Long Course —White Steamer Wins Free-for-all and Makes Best Time.

As is the usual case at hill climbs, the White steamer distinguished itself at Salt Lake City, Utah, last week. The Newhouse cup offered for a free-for-all event in the hill surmounting contest on Saturday, was easily won by Fred A. Dundee, driving J. F. Dunn's 30 horsepower stripped White touring car. The distance was 1½ miles up a 15 per cent. grade, and the steamer purred up the incline in 1:40. In the field against it were a Stearns, Stoddard-Dayton, Studebaker, Pierce Six and the "Blue Bird" racer. Following this performance, in a special match race, the same White won over a Stoddard-Dayton, making the climb in 1:40⅗.

The first event of the afternoon for electrics, went to a last-minute entry, the Fritchie, which was awarded the Keith cup, for getting over the ground in 5 minutes 10⅗ seconds, trimming a Studebaker and a Pope. The Mitchell captured the $1,000 class event without difficulty, and a Jackson got first position in the $2,000 class. In the $3,000 division, E. S. Yankee's Pope-Hartford won the equipped race, while the stripped chassis event was nipped by a Stoddard-Dayton.

C. S. Ruffuer's Stearns beat out a Stevens-Duryea in the equipped touring car event for machines listing at $5,000, and in the same class for stripped cars, a Stoddard-Dayton, entered by the Shannon Auto Co., won, making better time than two Stearns and a Studebaker.

The course extended up one of the steepest grades in the city, along Brigham street to the Government reservation. A sharp turn near the summit was calculated to supply the desired thrills for the spectators:

The summary:

Electric class—Won by Borkman Electric Co. (Fritchie); second, C. A. Quigley (Studebaker); third, A. O. Whitmore (Pope),. Time, 5:10⅗.

Gasolene cars, $1,000 or under—Won by Sharman Auto Co. (Mitchell); second, Maxwell. Time, 3:38.

Gasolene cars, $1,500 or under—Won by C. S. Higson (Jackson). Time, 3:37⅗.

Gasolene cars, $2,000 or under—Won by F. S. Murphy (Jackson); second, E. D. Miller (Kissel). Time, 3:07.

Gasolene cars, $3,000 or under—Won by E. S. Yankee (Pope-Hartford); second, F. S. Murphy (Jackson). Time, 2:29⅗.

Gasolene cars, $3,000 or under (stripped touring cars or runabouts)—Won by Sharman Auto Co. (Stoddard-Dayton); second, Auto Exchange (Jackson); third, Keith Clarke (Pope-Hartford). Time, 1:53⅕.

Gasolene touring cars, $5,000 or under—Won by C. S. Ruffner (Stearns); second, T. Botternell (Stevens-Duryea). Time, 2:01⅗.

Stripped touring cars or runabouts, $5,000 or under—Won by Sharman Auto Co. (Stoddard-Dayton); second, C. S. Ruffner (Stearns); third, H. B. Lamb (Stearns). Time, 1:49⅘.

Free-for-all—Won by Fred Dundee (White Steamer); second, Sharman Auto Co. (Stoddard-Dayton); third, S. Newhouse (Pierce-Arrow). Time, 1:40.

Special match race between two first cars in free-for-all event—Won by Fred Dundee (White Steamer). Time, 1:40⅗.

Oldfield Exhibits to Kentuckians.

At the Blue Grass Fair, Lexington, Kentucky's big annual summer event, Barney Oldfield did a stunt or two in the automobile track races. Monday, August 10, was Automobile Day, and eight events for all sorts of cars were scheduled. The feature of the afternoon was the match race between Barney Oldfield, driving a Stearns, and Charles Soules, for three laps around the famous trotting track. The cars were given a flying start and Soules had the inside rail, which he held all the way. Oldfield was unable to get past him until the home stretch was reached, when the Stearns flashed ahead, winning by a length. Barney's time for the three miles was 3:17.

Later in the day, both of these drivers made mile trials against time, from a flying start. Soules circled the saucer in 59¾ seconds, lowering the record for that track, which was formerly 1:01. Then Barney did a barn-dance around the course, covering the mile in 59¼, which over-shadowed the previous time by one-half second.

According to a Louisville despatch, "the first of the automobile races for amateurs was for motorcycles." The Kirby family won this event, R. W. being first, and H. N. second in a two-mile spin; time 3:05. An Oldsmobile with Suff, of Louisville, at the wheel, cleaned up a two miles fully equipped car event, getting over the ground in 2:46.

Soules captured the free-for-all handicap at two miles, winning over a three-quarters of a mile handicap in 3:11, Oldfield failing to start in this event. Two days previous to the race meet, Barney lived up to his sensational reputation by doing his old favorite trick of plunging his car through a fence. In this, Oldfield came out victorious as usual, smashing the fence to toothpicks and retaining only a few stratches.

Kansas City Re-elects President Cowan.

With a present membership of 229, including several new names enrolled at its annual meeting, the Kansas City Automobile Club has announced the re-election of W. W. Cowan as president. The official board is now made up as follows: President, W. W. Cowen; first vice-president, Elliott H. Jones; second vice-president, W. G. Coumbe; secretary, W. P. M. Stevens; treasurer, Frank J. Dean; directors, W. G. Whitcomb, Dr. E. M. Hetherington, F. P. Ewins, G. H. Davis, J. W. McKecknie, D. E. Gudgel.

PIPE DREAM OF RACE PROFITS

Lowell Automobile Club's Chief Calculator Foresees Financial Success for Big Race—Handsome Net Result.

Despite the indications of the succeeding paragraph this is not a lesson in history, but merely an historical introduction to the story of an arithmetical calculation.

Lowell is a bustling little Massachusetts city, situated on the Merrimac river. Its estimated population of 100,000 is domiciled within an area of 14 square miles. These people pay a tax rate of -1.94 on an assessed valuation of $75,445,738. It boasts not inconsiderable manufacturing interests and—the Lowell Automobile Club.

This club intends to promote an automobile road race on Labor Day, September 7th, as already detailed in these columns, and although more than one month distant, its Chief Calculator has the race already run, mathematically and financially.

Here is the table of expenses and resources of the race that is to be—or may be—as compiled by the Chief Calculator:

Expenses.

Erecting grandstand	$4,000
Erecting bandstand	400
Erecting judges' stand	200
Telephone service, five stations around the course	300
Oiling and fixing road, not to exceed.	1,000
Wiring off road, 10 6-10 miles, labor and material	350
Banners across roadway at turns and in city at depot	300
1,000 red and white flags	50
Caps and sashes for 500 men patroling course	150
Wages for men patroling course, 500 at $2 per day	1,000
30 megaphones	15
25 men to sell tickets, programs and score cards, $2 per day	50
Printing programs and score cards, advertising in program to pay for same	00
Bulletin advertising, printing and distributing	2,000
Incidental expenses	1,000
Insurance	500
Legal expenses	500
Music	300
Total	$12,145

Resources.

9,000 seats in grandstand at $1 each.	$9,000
100 seats at $5 each	500
50 boxes seating six at $25	1,250
10,000 programs at 25c each	2,500
10,000 score cards at 10c. each	1,000
Parking 2,000 automobiles on side roads at $2.50 each	5,000
Parking space to peddlers for sale of eatables, tonics, candies, popcorn, peanuts, etc., and advertising spaces	2,000
Entrance fees, 12 cars at $250 each	3,000
Revenue for vitagraph machines	1,000
Total resources	$25,250
Total expenses	12,145
Profit	$13,105

Digitized by Google

ENDURANCE RUN OF AN ELECTRIC

Thousand Miles Journey Successfully Accomplished by a Runabout—Big Daily Average Over Varied Roads.

Electric runabouts, as a rule, are not expected to serve as vehicles of transportation for long distance runs. The entry in an endurance contest of a car of this description would excite more than the usual amount of comment, and while cars of this type repeatedly have made excursions to points 40 or 50 miles distant from their home city, such trips have been either experimental or have been undertaken in an emergency. But despite the reason of, or cause for, these so-called long distance trips, it yet may be asserted that a thousand mile run of an electric runabout has,

BETWEEN DETROIT AND TOLEDO

until very recently been considered an exceedingly difficult undertaking.

Such a journey has recently been placed to the credit of a small electric vehicle. Such a car has traveled from the middle west over rough roads and through hilly country to the eastern coast of the United States.

From Detroit, Mich., to New York City is an approximate distance of 1,000 miles. For an electric car to make so long a trip must be considered more or less a feat of endurance. Endurance runs for electrics had been accomplished before, but this particular journey never had been attempted until July last, when a "Detroit Electric" runabout started from Detroit, when it reached New York on the night of the 23d inst. The little car made its long journey with one set of batteries, charging, of course, along the route. The daily average was 85 miles. From New York the car went to Philadelphia and Atlantic City, from which place it will be shipped back to Detroit and placed on exhibition in the show rooms of its makers, the Anderson Carriage Co.

Two illustrations of the car on its long trip are shown herewith. In one of them may be seen the difficult roads which were encountered between Detroit, Mich., and Toledo, Ohio. The other picture illus-

HILL 20 MILES FROM ERIE

trates the car climbing a steep hill about 20 miles out of Erie, Pa. Equally adverse conditions were met from time to time during the journey and the successful completion of the trip under the conditions which prevailed is distinctly noteworthy.

Nevada Method of Road Building.

Roadmaking usually is considered a science requiring much study and the possession of more or less elaborate machinery. In Nevada, the process of building a road does not entail much book learning or the use of other than home made implements. Dr. Miller of Rawhide, who is running an auto stage from Rawhide to Schurz, makes roads by dragging timbers fitted with cutters over the desert. Twenty horses are hitched to the improvised roadmaker, which levels the sand, cuts the sage brush and makes a fairly good imitation of a road, all in one operation.

For Sightseeing in the Ogden Canyon.

"Rubberneck wagons" in the Ogden Canyon are the latest development in the sightseeing line. The automobiles will be operated over the road beginning at the mouth of the canyon and running in as far as the Oaks. The company which will operate the line has filed articles of incorporation with the county clerk under the name of the Ogden Canyon Automobile company. It anticipates liberal patronage from tourists who do not own automobiles.

PHILADELPHIA'S NEW CAB SERVICE

Quaker City Adopts the Taximeter Vehicle for Public Service—Festal Inauguration of the Local System.

Not long ago the city of Brotherly Love saw a taximeter cab skidding around Broad street. Soon another cab of the same species began to cavort around town and shared the novelty with the first one. Then another put in its appearance and things began to grow serious. But the formal introduction of motor cabs for service at the hotels and railroad stations of Philadelphia, took place on Wednesday, July 29, when President Claude S. Jarvis of the Quaker City Cab Co. held inaugural festivities. Mayor Reyburn and two score other prominent persons, political and otherwise were

PHILADELPHIA'S CAB BRIGADE

the guests of Mr. Jarvis on a short run in brand new taxicabs, to one of the city's leading hotels, where luncheon was served.

The new cabs are of American Locomotive make, have deep yellow running gear and dark brown bodies, and are similar to those of the same make in operation at the Waldorf-Astoria in New York. The motor is a four-cylinder, vertical type, 16 horsepower, and the chassis has a wheel base of 103 inches, with a 55-inch tread, and weighs with body attached, 2,600 pounds. Shaft drive is used.

Stage Line to be Extended.

Having been successful, the automobile stage line which has been in operation between Plainfield and Boynton Beach, N. J., will be extended to take in South Plainfield, Metucken, and Perth Amboy. The car, which will carry 12 passengers, will make two trips each day. It is owned and operated by the Thompson Automobile Co. of Plainfield.

PRINCIPLES OF PATENT LAW

Legal Light on Their Creation of Monopolistic Rights—Differences Between American and Foreign Systems.

An unusually brilliant elucidation of the principles of patent law is given by Edwin J. Prindle, in a lecture delivered before the New England Society of New Jersey and recently quoted in these columns to the extent of defining what a patent really is. The monopolistic feature of the patent was the most striking point brought out in that connection.

"This monopoly," says Mr. Prindle, "is the reasonable price the public pays for the invention; or rather, it is a way by which the inventor is permitted to pay himself, if he can, for his invention, by supplying it to the public to the exclusion of others, for a limited time, after which the public has the unrestricted use of the invention, which actually cost it nothing. The wonderful material advances from the days of our grandfathers (greater than the sum of all the ages before) is due to the encouragement of the patent laws."

With regard to the material point of patent claims and their relative weight, he continues:

"The claim of a patent, because it conveys a negative monopoly, is one of the most peculiar of all pieces of English composition. The more it says the less it means. It is like a bill of sale for cattle on a Texas ranch. If it purported to give title to all the 'short horned Durham steers with one white foot and three black ones,' it would convey perhaps only two or three steers, while if it said simply, 'all the cattle' it would convey all the steers of every kind, and all cows, bulls, horses and pigs. It might also be likened to a monopoly of everything that would fit into a box. If it said a 'round box having a pin stuck up in the middle,' only round things with a hole in the center would be included in the monopoly (only wheels and doughnuts), while if it said simply 'a box' not only would everything be included that would go into the round box with the pin in the center, but also everything that would go into a round box without the pin, a square box, an oval box, a star-shaped box and every other kind of a box. Therefore, the less a claim says the more of a monopoly it conveys.

"There are thus upper and lower, or maximum and minimum, limits to be avoided in a claim. It must not be so broad as to include earlier forms that were not invented by the patentee, and it should not be so narrow as not to include all possible embodiments of the soul of the invention.

"Having gotten his patent, what can the patentee do with it?

"The court will grant him an injunction against any one who makes, uses or sells any embodiment of the invention. The court will also award him damages for any sales he can prove he lost through the interference of the infringer. It will also award him any profits he can prove the infringer made through the use of his invention. The most valuable of these remedies is that of suppressing competition by injunction.

"When a suit is brought on a patent, the defendant may show, if he can, that the patent is invalid. He may set up any one of the following defenses: That the patentee is not the original and first inventor of the patented invention; that the invention was known and used by the public before it was invented by the patentee; that the invention was described in some publication more than two years before the application for patent was filed. He may also show his machine does not infringe the patent. . . . .

"Not only will the court, by its final decree, grant an injunction to the patentee in a proper case, but, under some circumstances, it will grant a temporary injunction at the outset of the suit. If the patent has been previously sustained by a court, even in a suit between different parties, or in case the public generally has acquiesced in the validity of the patent, the court, in the absence of a very strong showing of new evidence against the patent, will grant a preliminary injunction. As patents are granted in this country only after a careful examination of the prior art by the officials of the Patent Office, and are therefore presumably valid, a preliminary injunction in the absence of a strong showing of anticipating prior art should be granted whether or not there has been a previous adjudication and whether or not there has been a public acquiescence. The United States Court in New York City is tending in this direction, but in this respect it is an exception. The requirement of a previous adjudication or public acquiescence as a prerequisite to a preliminary injunction is an inheritance from the British patent law, where a good reason existed for these requirements, namely, that as there was no examination made as to the novelty of the invention before granting the patent, there was no presumption the patent was valid. During the early years of our patent system, no examination was made, but now that such is the fact, the patentee should not be treated as though his patent were presumptively invalid and made to wait until the termination of a perhaps protracted suit before getting any relief from the infringement of his patent.

"Those who seek to appropriate an invention without paying tribute seldom make Chinese copy of it. They usually make something which, at least, avoids the terms of a claim. So the courts adopted what is known as the "doctrine of equivalents," under which the inventor is entitled to include within his monopoly not only everything which is described by the language of his claim, but everything which is the mechanical, chemical or electrical "equivalent" of what is claimed. This term "equivalent" is necessarily indefinite and it gives the court an opportunity to do what it considers to be equity in the particular case.

"The monopoly granted by a patent is a very convenient one. It includes the three separate branches of the right to prevent others from making, or from using, or from selling the invention. These three rights can be granted either separately or together. . . . . .

"Our own system will be better understood by a brief comparison with some of the principal foreign systems. In America the Patent Office, as I have before stated, makes a careful examination before granting the patent to see that patents are granted only for novel inventions and that the claims are restricted to a monopoly to which the inventor is justly entitled. Thus our patents have a prima facia validity. France, on the other hand, makes no examination before granting a patent, and requires no claims. England has only just begun to make preliminary examinations. Germany subjects applications for patents to a very rigid examination. The United States requires no taxes of the patentee after his patent is granted, as the price of keeping his patent in force for the 17 years. England, on the contrary requires taxes paid annually after the fourth year, and Germany and France require annual taxes. The United States does not require the patentee to put his invention into commercial use, but France and Germany absolutely require it, and England will invalidate a patent for an invention which is manufactured chiefly abroad but only slightly or not at all in England. In the United States, any of the defenses to a patent can be raised in answer to a suit for infringement, and that at any time during the life of the patent. In Germany the only answer to a suit for infringement is a denial of the charge of infringement. If the validity of the patent is to be attacked, it must be by a separate suit for annulment, and such a suit can only be brought during the first five years of the patent. Therefore, after a German patent is five years old, it is conclusively presumed to be valid. In the United States, if one claim of a patent having several claims is proven invalid, that does not affect the standing of the other claims. In England, however, if one claim is proven invalid, the entire patent falls."

"It is perfectly safe to say the American patent system is a permanent part of our jurisprudence, and that future legislation will not be in the direction of curtailing the rights of inventors, but rather of encouraging them by making the enforcement of their rights a matter of less expense and time."

WINTON INVENTS A TWO-CYCLE

Cleveland Manufacturer Protects Regulating Device for Multiple Cylinder Engine—Features of the Design.

For some little time there have been no developments in the field of two-cycle design which would lead to the supposition that well-established manufacturers of the more familiar type of motor were contemplating a swing in this direction. Nevertheless, the possibilities of the two-cycle motor are so alluring that it would not be surprising were a constantly increasing amount of attention paid to its use in the

future, especially when the successes of the small number of makers who have adhered to it up to this time is considered. On this account considerable speculation may be aroused by the announcement that a patent was issued last week to Alexander Winton and Harold B. Anderson, Cleveland, Ohio, "assignors to the Winton Motor Carriage Co.," and covering a form of "multiple-cylinder two-cycle explosion engine."

One of the difficulties encountered in the construction of multiple cylinder motors of this type hitherto, has been that of securing proper carburation for all the cylinders, with the use of but a single carburetter. Indeed, this difficulty has been so much more serious in its effects than has been the case with the multi-cylinder four-cycle motor, that it has been found necessary in some instances to employ two or more carburetters or mixing valves for the purpose. It has been suggested, however, that by arranging for the dilution of the charge independently in the case of each cylinder, the differences in suction from the various cylinders may be better equalized and a more uniform performance ensured.

This, in a word, comprehends what is apparently the chief purpose of the new Winton arrangement. The claims of the patent stipulate:

"The combination with a multiple-cylinder, two-cycle explosion engine, of a single carburetter having a supply communication for each cylinder, and means for admitting regulated volumes of air to one of said communications independently of both the carburetter and the other communication."

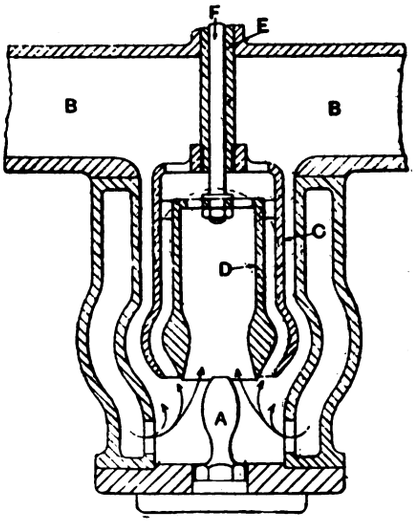
The accompanying illustration shows the general arrangement contemplated. The usual three-port cylinder construction is shown, also provides for the attachment of the carburetter, 2, to the cylinder, 1, at a point where a small chamber communicates with the regular crank case intake port. The throttle, 4, is placed outside the diluting or mixing valve, the latter revealing an air intake at a, and an adjusting screw at b, whereby it is possible to arrange for a permanent modification of the quality of the mixture, such as may be necessary to ensure a perfectly uniform performance in all the elements of the motor.

Adjustment of the Pet Cocks.

Considerable importance is attached to the proper adjustment of the several small pet cocks which are distributed in various parts of the car. If they are permitted to become sufficiently loose so that they will turn freely, there is danger that they will be opened by the vibration of the machine. The result will be the wasting of oil or water, from the cooling system or crank case, as the case may be, or a considerable loss of fuel, if the drain cock on the gasolene line happens to be affected. In the case of the shut off from the fuel tank or the pet cocks on the cylinders, any difficulty of the sort is immediately manifested in the running of the machine. In other quarters, the only evidence of trouble arises from indirect results, such as frequently may be of a harmful nature.

Care of the Floating Axle.

Rear axles of the full-floating type are frequently "built up" of a number of separate sections, including the axle tubes, the central or body section, housing the differential gears, and the torsion tube which encloses the propeller shaft. It is absolutely essential that these parts be retained in their proper alignment, and that they are not permitted to "work" through the relaxation of the bolts which secure them. Particularly when either of the parts has been dismounted for any reason, it is necessary to make sure that in reassembling the proper relation of the parts is not lost.



Safely Locating the Shut-Off.

Motor car designers should be especially careful in locating pet cocks or shut-offs to see that they are so placed that there is small danger of their being accidentally disarranged by the clothing of the repairer or driver, or from other causes. The results of such movements are not necessarily serious in their consequences. But they constitute a cource of annoyance.

INGENUITY IN A MIXING DEVICE

Concentric Tubes of Variable Area the Feature in New Foreign Carburetter—How the Flow is Regulated.

Whatever may be said of the success of modern carburetter design both from the standpoints of economy and smoothness of operation under all conditions of load and throttle opening, it is perfectly evident that no complaint can be made on the ground of lack of variety in method of attack. A really astonishing point, however, is that despite the wide variation in method, and the complexity of the requirements involved, a

marked uniformity of action has been attained. In this connection, it is interesting to note the latest development of the Daimler Moteren Gasellschaft, in which the use of the familiar venturi tube has been supplemented by a couple of concentric passages, so contrived that their respective sectional areas may be altered at will, to vary the relative velocity of flow.

The mechanical construction of the device is shown in the accompanying illustration in which the jet nozzle is shown at A, and the induction pipe at B. The spray chamber is broken up by the introduction of the two sleeves, C and D, both of which are adjustable in position. One is moved by means of the sleeve attachment, E, in the vertical sense, and the other is actuated by means of the rod, F. The lower ends of the sleeves are expanded into the peculiar bulbus form, shown.

The two sleeves are actuated independently of one another, either by automatic or manual means, and constitute the entire control of the quality and quantity of the mixture fed to the engine. By moving one of the sleeves in relation to the other, the opening between them is varied, while by moving both together, the area of the passage outside the tube may be varied at will. Altering the position of the rods E and F,

Digitized by Google

thus controls the flow of air directly over the jet, and so the suction and lift of fuel into the mixing chamber above, and also the flow of air in the outer passage, thus regulating the amount of dilution which is to be given the rich gas in order to produce the correct firing mixture at the point of delivery to the engine.

A point which is to be observed in this connection also, is that while of unusual form, the parts involved are comparatively simple in construction. This is a characteristic fairly general with modern types of carburetter. In this respect most of them are in sharp contrast to many of the older types, in which the same results were obtained only at the expense of considerable complication, which happily has now come to be recognized as needless.

An Accessory for Night Travel.

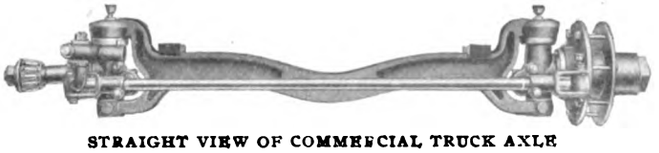
While adding accessories to the regular equipment of the car is a form of "tinkeritis," which it usually is well to avoid, it sometimes occurs that some slight addition can be made which is of distinct merit. Such an addition is an electric light which will serve to illuminate the dial of the pressure gauge connected with the gasolene tank on cars which are not designed for gravity feed to the carburetter. The small lights rated at one-fourth or one-half candle power easily may be attached to the dash board in such a position as to throw their ray on the dial; a piece of tin or sheet brass should be shaped and attached to the light so that the operator cannot see the filament; the electrical connection may be made to the batteries through a push button, the latter within convenient reach of the driver. When traveling in dark roads or through unlighted streets it only is necessary to push the button and the position of the gauge hand may be seen and by this means the driver of the car can maintain an even pressure on the tank at all times.

Practical Hints for the Operator.

Where the connection between steering knuckle and reach arm is maintained by a pin held in position by a cotter, it is well to keep careful watch of the latter and to replace it with a new one when it shows signs of wearing.

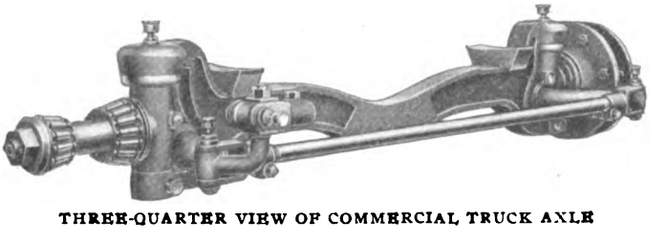
As the custom in refilling grease cups is to replenish the supply without removing the grease which remains in the cup, it is obvious that some of the lubricant may remain in one place for a very long time. Occasionally this grease should be removed and the cup thoroughly cleaned and freed from all verdigris and possible accumulations of dirt before being refilled.

In inserting a tire valve through the rim, the shoe should be held in such a position as to permit the stem to enter the hole easily. Unless this precaution is taken there is danger of straining the inner tube at the point of connection of the stem with the result of developing more or less serious leakage.



FRONT AXLES FOR MOTOR TRUCKS

New Timken Product for Use in Heavy Vehicle Construction—Details of Its Anti-Friction Mounting.



One of the most encouraging symptoms of the progress which is being made in the development of the commercial vehicle is the amount of attention which is devoted to the evolution of special forms of component parts by the makers who specialize in this line. Recognizing in the business automobile not simply a fruitful opportunity in the commercial sense, but also an opportunity for profitable effort in the production of elements which shall combine durability and strength with a minimum of running expense, several parts manufacturers already are bringing out new things in this line from time to time. Typical in this respect, is the new commercial vehicle axle which has just been introduced by the Timken Roller Bearing Axle Co., Canton, Ohio, a firm whose enterprise in this quarter, it should be mentioned incidentally, has been rewarded with an even greater amount of patronage than has been secured in the field of the pleasure vehicle.

TOP VIEW OF COMMERCIAL TRUCK AXLE

STRAIGHT VIEW OF COMMERCIAL TRUCK AXLE

THREE-QUARTER VIEW OF COMMERCIAL TRUCK AXLE

As in the lighter models of front axle produced under this mark, the objective of the designer has been to combine the greatest possible load-carrying capacity per unit of bearing with the required durability, as well as resistance to load and end thrusts—the latter being a class of stresses which are especially to be guarded against in vehicles which are to be heavily laden. Just how this has been accomplished, the accompanying illustrations are well calculated to reveal.

The axle proper is of the conventional I-beam type, slightly dropped in the center and carrying unusually heavy yokes for the reception of the Elliott type knuckles. The pads upon which the spring seats are mounted are forged integral. The seats themselves, however, can be located as desired. This permits considerable latitude of design without involving any modification of the axle and greatly increases its adaptibility. The great range of center to center widths thus provided for is best shown in the top view of the axle.

The axle is entirely roller bearing mounted. That is to say, the anti-friction provision is carried out even in the steering connections, which is most important considering the amount of dead weight which must be carried and the slow rates of speed at which it is to be driven. The standard conical type of bearing is employed throughout, and is used not simply in the axle stubs, but in the steering knuckle heads, where the actual support of the load is concentrated, and the universal joint steering connections. Hardened and ground steel bushings are employed and grease cups are fitted at all points where regular lubrication must be assured.

It will be observed that the axle is arranged for the usual cross steering layout common in vehicles of this type, no separate steering arm being required for the attachment of the connecting rod. Instead it is coupled directly to one of the arms to which the cross bar or link is attached, thereby simplifying the construction.

The outside dimensions for the standard section are 2½ inches width and b inches depth. It is figured for a load, including the axle weight of the vehicle, of 18,000 pounds.

PENAL CODE REACHES JOY RIDERS

Unwarranted Use of Employer's Car Lands Chauffeur in Prison—First Case of the Sort in New York.

While no law exists in New York State enacted solely for the purpose of protecting automobile owners from "joy riding" employes, it has been discovered that a section of the penal code may be used as a basis of action against chauffeurs for using their employer's automobiles without permission. The first man to receive sentence under this act, for the unsanctioned use of a motor car, was Charles A. Terrell, of New York City, who, on Wednesday last, was sentenced by Justice Wyatt in the court of Special Sessions, to serve thirty days in the city prison.

Terrell had been arraigned under section 675 of the penal code, which forbids the wilful or malicious destruction of property. It was charged by his employer that on the night of August 3d, the chauffeur had taken the automobile from the garage without permission and accompanied by a party of friends, had used the car for 30 hours. It further was alleged that by reason of this trip the car had suffered damage to the extent of $100 for wear and tear and the expenditure for gasolene.

After a trial, Terrell was found guilty, and Justice Wyatt said in pronouncing sentence:

"Hereafter any automobile owner that will come here and swear that his machine has been damaged to the extent of 10 cents by reason of a chauffeur's using it without permission we will, if the evidence warrants it, find a conviction under this section and impose sentence. Let this be a warning to all chauffeurs who go on larks at their employer's expense."

Cape Cod Favors Motorists.

Cape Cod folks are manifesting a spirit of fairness toward motorists that is being reciprocated by a very general observance of the law on their part. The town of Hyannisport has adopted a new and so far successful way with the reckless and fast automobile tourists. First, the special officers of the town tell them when and where they can run fast, but warn them that if they are caught running at a reckless speed around curves or through the villages they will be arrested and taken to court. While hundreds have been stopped and warned not an arrest has been made since the adoption of this plan.

The town of Sandwich has increased the speed limit in the villages five miles, making it now 15 through the thickly settled parts and 25 on the outlying roads. This is said to be one of the fairest towns in the State to the automobilists, and they appreciate it, as there has not been an arrest made, and not a single automobilist has had to be warned against exceeding the rate of speed permitted.

Fatal Touring in Death Valley.

Two Californians, resident of San Francisco, who attempted to cross Death Valley, Arizona, in an automobile, failed miserably in the attempt, which cost the life of one of them and would have proved fatal to the other but for the timely arrival of a rescue party. The two men, F. D. Spaulding, an automobile dealer, and T. P. McCauley, undertook a short cut across the desert at Gila Bend, on the 31st ult., against the warnings of friends who well knew the perils of such a trip in a heavy motor car at this time of the year.

They did not arrive at Gila Bend when they were due, nor did they return to Yuma, and a squad of rescurers equipped for the purpose, set out upon the trail of the machine. They found it stalled in the sand, and lying beside it, in the full glare of the sun, the victims of the unwise attempt.

The rescue party promptly set about trying to restore life to the two men, and finally succeeded in reviving McCauley. Spaulding, however, died five hours later, just as the party was entering Yuma.

Farmers Set Double Traps.

Farmers in Mercer County, N. J., have determined to put a stop to the speeding of automobiles on the roads passing through Trenton. Already several arrests have been made and in all the cases fines have been imposed by Justice of the Peace Narr. The farmers say it is impossible for them to have their windows open because the speeding automobilists raise dust which enters their homes. Two weeks ago the farmers hired men to mark off a mile of road. The agents of an automobile company warned automobilists of the speed trap. The farmers let the automobile men watch the speed trap, and hired other men to go into another part of the county, though on the through road from Philadelphia to New York, measure off another mile and lay for automobilists.

How It all Happened.

Should the Edwards county farmer, who may have found the seat of a pair of trousers hanging to his barb wire fence, send it to this office, says an Edwards county paper, we will see that he receives pay for the row of corn knocked down by a Mitchell car. The mud hole in the road was deep, and the only way to get around it was to cut the barb wire fence and smash about 200 yards of corn, which would have been paid for on the spot had not the farmer appeared with a shotgun while swearing a blue streak. There was really nothing left for the boys in the car to do but to cut the fence a second time and skip; and in the skip one of them lost a quarter section of his trousers. But then they will pay for the corn when the proof is furnished.

CHAUFFEURS TAKE UP POLITICS

Their Club Pledged to Active Work in National Campaign—The Purposes They Aim to Serve.

"Having decided that "automobile drivers are most loyal supporters of that which is right, just and fair, the Board of Governors of the Professional Chauffeurs Club of America, in meeting assembled, resolved that "the organization take an active and energetic part in the coming campaign for the election of a president of the United States." It also was decided that "there is hardly any other collection of individuals that can do more to bring about the election of a President."

As a basis to work upon, the board of governors adopted an automobilists' political platform, which is subject to modifications. This platform is as follows:

1. Fair laws and their administration to all.
2. Abolish prosecutions for technical violations of law.
3. Prosecute and punish reckless automobile drivers.
4. Abolish vicious speed traps and prosecute persecutors of the motorists.
5. Legislate against graft.
6. Protect the hotels, garages, automobilists and the people against the enactment of unwise and destructive legislation.
7. Place impartial judges on the bench and just executive officers in the positions of public trust.
8. Remove biassed judges and unscrupulous officers.
9. Work for good roads.
10. Compel a sane use of the highways.

Registration Lively in California.

From the office of the Secretary of State of California the report is made that during the month of June 519 motor vehicles were registered. In the same month 159 licenses were issued to chauffeurs, 82 transfers of licenses were recorded, and 14 duplicates issued to dealers. The amount of money collected by the State automobile department for the month was $1,517.

Automobiles in Mining Camps.

Automobiles are extensively being used for the transportation of men and ore in the mining country of northern Wisconsin, Minnesota and upper Michigan. The cars are operated between the various range cities andperform an especially useful service in carrying supplies.

New Jersey Has Second Largest Club.

With 1,121 members on its rolls, the New Jersey Automobile and Motor Club now is the second largest club in America. The Automobile Club of America, of New York City, stands first.

The Cars In the

BRUSH RUNABOUT EFFICIENCY RUN

had progressed up to Saturday morning as follows:

They have covered about 100 miles per day, giving numerous demonstrations in towns and cities passed through. and being received everywhere with the keenest interest and evidently great enthusiasm.

So far no mechanical troubles of any kind are reported. Casualties consist of one dog and one rooster. The running time is averaging from 17 to 22 miles per hour, gasolene consumption running 23 miles per gallon, and oil consumption running 110 miles per quart. As all motors were new and still at the start, the fuel and oil consumption would doubtless be cut down before the finish. Each car carries besides two passengers, baggage for two weeks, about sixty pounds of cuts and literature, oil, tools, tire chains, etc., making an extra load of about 175 lbs.

The Model B Runabout is a wonderful little car. It is not a copy of something else, nor a big car boiled down with the same number of parts only smaller, nor an appeal to vulgar fadism, but is built strongly and sanely to do its own work in the best possible way. For one or two passengers it does all the big cars do, barring speed above thirty miles an hour and at absolutely the minimum cost and the maximum convenience.

The Model B has refined and graceful lines, such as are seen on no other small car. Its running qualities are unapproached and unapproachable by any other, big or little. Its motor is as lively as a humming bird, but as persistent as a mule. Its transmission is perfectly quiet, self adjusting, and the most durable part of the car. Its clutches are positive and absolutely without jar.

You have heard numerous things said about the Brush Runabout both good and bad, from friends and supposed competitors. The only real valuable opinion is that of an owner. Ask any owner all about it. If you don't know one we will give you some names. Deliveries start this week. Orders are coming fast and we want yours as soon as possible.

This Run is to demonstrate the

MODEL B BRUSH RUNABOUT

On Pneumatic Tires, $550. **On Solid Tires, $500.** **500 pound Delivery Wagon, $600.**

SWELL BACKERS OF "PIPE LINE"

American Millionaires with British Peers in Association to Cut Prices of American Accessories—Trade Menaced.

Makers of accessories who have a sale for their products in Great Britain, and bargain seeking automobilists who have a fondness for high society and a weakness for joining associations that promise cut prices, are bound to feel an interest in the "Automobile Co-operative Association of America," which describes itself with succinctness and alliterative turn as being " a combination of motorists to buy at greatly reduced cost everything from cars to cotter pins." While superficially it appears to be only for the benefit of Americans, it presents very unpleasant trade possibilities in connection with the sale of American automobile goods in England and on the Continent.

August Belmont is chairman of the advisory committee of the association, and other names almost equally famous are on the list, including James L. Breese, of Havre-de-Grace, Md.; Joseph H. Emery, of Lord & Taylor, New York; Gustave B. Fletcher, of Philadelphia, and more of the kind. By reason of the fact that the association is practically a branch of an English organization of the same character, which latter has been in operation for some time, an overwhelming list of British names and titles are also conspicuous on the prospectus, including an array of earls, lords, lieutenant-generals, right honorables, colonels, sirs, viscounts, bart.'s, K. C. B.'s, D. S. O.'s, M. Inst. C. E.'s, and the like that is perfectly thrilling.

Almost any plain ordinary American citizen who has $8 to spare can become associated in business with this international galaxy if he be so minded, because the organization has stock for sale—as many shares as anybody wants to purchase. The stock costs $5 a share and the annual dues are $3.

"On behalf of its members," the prospectus states, "the Association acts as purchasing agent for all kinds of cars and motor boats, and for component parts, accessories, tires, tools, apparel and supplies. Buying from the manufacturers its profits are applied in dividends to its members."

The danger to the American accessory maker in having his prices cut abroad is indicated by the next paragraph, which in continuance, says: "The Association is affiliated with the English Association of the same name and purpose, members of each having the privilege of the other. Offices are maintained in England and the principal Continental cities, where cars and supplies can be obtained at Association rates.

"This Association," the prospectus continues, "comprising as it will many thousand members, will constitute such a purchasing power as to command discounts beyond the reach of motorists through any other channel. In this manner chauffeurs' commissions will be entirely eliminated."

However indifferent the success of the Association may be in gaining an extensive membership in the United States, it will serve as an excellent "pipe line" for the English association in getting American goods at lower prices than the authorized agents on the other side now charge. The sale of American clocks, lamps, speedometers and similar accessories in London particularly, has grown to big proportions. If low trade prices are granted to the New York office, the goods will be slaughtered on the bargain counters at the immense cut-price establishment which the Association conducts at 1 Albemarle street, Piccadilly.

Warns Against Cut Rate League.

In an effort to protect its members from the wiles of those who seek to obtain patronage by representing themselves as being affiliated in a business way with the organization, the trustees of the New Jersey Automobile and Motor Club of Newark, N. J., have adopted measures which they believe will put an end to an evil which has devloped into a public nuisance. Throughout the State, and in fact the country, there has been a development of so-called leagues which claimed some sort of relationship with about every legitimate automobile organization in the United States.

In many cases the leagues are conducted by persons who purchase goods at the lowest possible figure, and by offering a small discount reap a harvest from the autoists, who are led to believe that the inducement is really worth their while and is offered through their membership with the automobile club, while as a matter of fact the circulars are mailed broadcast to every automobilist whose name is received through the State department of motor vehicles when the license is granted.

The New Jersey organization took official notice of the matter Monday night, when a resolution was passed declaring that it was the sense of the trustees that the members of the club will derive no benefit from any relations with certain private automobile leagues which are promoted for private profit.

Promoter Charged with Embezzlement.

Harland Norwood, promoter of the "Community of Automobile Interests," an organization to provide automobile accessories to consumers at favorable figures, was arrested on August 7 at Newark, on a warrant charging him with embezzlement. The charge was made by the Greene Motor Car Co., of Newark, and alleged that Norwood, while a salesman in their employ, had been forgetful about turning in receipts for sales. Norwood, who was released on bail, promises to explain everything satisfactorily.

BOOSTING THEIR BARGAIN COUNTER

The A. C. A. Drums up Trade by Circularizing Members—Alluring Offers of Cuts from Current Prices.

Having for a long time entertained itself with the gentle delusion that it has been "fathering" the automobile trade, the Automobile Club of America some months ago felt the itching to indulge in a little dabble in trade itself, and to that end opened an automobile supply store on the third floor of the club house. To stimulate sales a circular about the store has recently been sent to the members of the club by the "executive committee," proclaiming it as a "cut price" place and soliciting more business than the members have been giving it.

The club's supply store aims to give its customers "large discounts from current market prices on all supplies according to the circular sent out and it further asks all the members to make price runners of themselves by reporting the quotations made by other cut-price houses so that the club's store may readjust its list of prices to meet them.

A large stock of tires and all automobile accessories is to be kept on hand, and the club store holds itself in readiness not only to fill orders over the counter, but to take care of mail order customers as well. A copy of all the quotations given the chauffeurs will be mailed to their employers so that the latter may make "comparison with other quotations" or bills.

Lively competition faces the club's cut-price store in the number of other houses already seeking trade on this basis. Some of the latter have peculiar and unusual facilities for getting automobile supplies for almost nothing and sometimes employ curious methods, not to say questionable, methods of obtaining them.

Not all of the members of the club approve the idea of its going into the cut-price business. There are those who believe it is not quite the function of a club to set about merchandising and cutting prices in the field in which it affects to hold a social and sport relation. Furthermore the installation of a cut-price store in the club house building was made a purely "ex-executive" action, without a consultation as to the will or consent of the members as a whole. That men like President Gary, of the steel "trust," whose chief activities for some time have been devoted to keeping up the price of steel, should divert their time to establishing a cut-price supply house in the club's building, is made the subject to more or less comment.

Whether the outside cut-price houses will be able to run the club institution off its feet, despite the backing and efforts of the "executive committee" on its behalf, remains to be seen.

MUST IMPROVE GARAGE RECORDS

Requirements of Massachusetts Law to be Enforced on Dealers—Joy Riding Chauffeurs to Lose Licenses.

Under the powers conferred by the present automobile law the Massachusetts Highway Commission purposes to check joy riding by chauffeurs and to hold dealers to account for imperfectly kept garage records. Chauffeurs proven to have taken out cars without permission of the owners will in every case lose their licenses. As to the dealers, the number allotted to each to be displayed on the cars his employes may operate on the roads is the means adopted by the State authorities for exercising the same check over a group of cars controlled by one man as is possible over a single car individually owned. It makes the dealer responsible to the State properly enough, and unless the dealer is ready to live up to the requirements of the law as to keeping a record, and thereby making it possible for the authorities to pick out the chauffeur who is the real offender in cases of abuse of these privileges, the Commission's only recourse will be to come down on the dealer himself.

It is an evident fact that the garage record book has been regarded more or less as a joke among the automobile fraternity. Yet certain cases recently before the commission have shown the book to be such an important factor in preventing accidents and road abuses that from now on the garage manager who fails to live up to the law and keep accurate tab on the men and cars for which he stands responsible will be taking a serious chance. It is not to be understood that anybody at the offices of the Commission has attempted to take a threatening attitude in the matter. Rather, it would be fairer to say that the commissioners seem to feel that when the dealers once appreciate the bearing of the record book on the subject of complaints and abuses they will be glad to co-operate in keeping the records as nearly accurate as possible, without any easy going lapses. Otherwise the logic of events will soon bring it about that a careless record book at the garage will mean a suspension of the dealer's license as a matter of course.

The chief point in the whole matter is that unless the garage record is kept with regularity and care, the dealer's number comes to be a cloak for the kind of road experiences that foster complaints and anti-moto sentiment among the public at large as well as before the commissioners.

Sheriff's Badges to Cure Speeditis.

Appointing automobilists to the office of deputy sheriff is the odd plan which has been adopted in Monmouth County, N. J., as a remedy for the propensity to crowd too many miles into the hour. Three men well known in Wall street are the first victims of this shrewd device and their fellow travelers on the Long Branch boats indulge in facetiousness at their expense.

Frank Savin and Monroe Rothschild, it appears have been among the most enthusiastic automobilists in the "Little Wall Stree" of Long Branch for several years. Both are good drivers and in days gone by have sent their machines at rapid clips down Ocean Boulevard. Incidentally considerable rivalry existed between the brokers as to who was the better machine driver. This rivalry caused Mr. Savin to make so many practice spins at such a rapid rate that they made him sheriff of the county. The residents, it is said, figured it out that the only way to make the broker drive slowly was to make him the sheriff. Mr. Savin, although proud of the honor, was distressed just a little because the title prevented him from honestly indulging in speeding. But the rivalry did not die.

Finally, unable to bear the strain any longer, Mr. Savin told Mr. Rothschild he would "go him" for a short trial anyway. The latter agreed and a date was set. The day before the event Mr. Rothschild was made a deputy sheriff at West End. Both were now officers of the law and any speeding was out of the question. Just who started this sheriff system of curing brokers with a predilection for speeding no one has been able to figure out. Robert Guggenheim, son of Daniel Guggenheim, is another who has been made a deputy sheriff.

Automobile "Prairie Schooner" En Route.

With a sort of prairie schooner body, equipped with a gas stove, ice box, cooking utensils, fishing tackle, guns and such other paraphernalia as conduce to human comfort, a White steamer belonging in Baltimore, Md., is following Greeley's advice and going west in the same rambling fashion as did the vehicles of the early settlers. The "schooner" is inhabited by George Snavely, of Baltimore, and his wife, who are vacationing overland. They left Baltimore three weeks ago and have reached Kansas City, whence they will motor to Abilene, Kan., then to Denver and Yellowstone Park. On the return the route will be through Minneapolis and Chicago, the plan being to reach Baltimore early in October.

White Issues Route Book No. 7.

White Route Book No. 7, just issued, contains detailed directions for touring between Chicago and Buffalo. With previous issues of this valuable series which the White Company has undertaken, complete and authentic information concerning the roads between New York and Chicago are now furnished for the first time. The new route book also contains road directions from Harrisburg to Cleveland, via Pittsburg, and from Pittsburg to Washington, Pa., where it connects with the routes described in Book No. 6.

EXTRA PERILOUS GRADE CROSSINGS

Danger Spots on Roads in Westchester County, Long Island and Staten Island —Warning List for Motorists.

Calling attention to grade crossings, which they designate as "extra hazardous," the Automobile Club of America of New York, has issued notices to its members giving the location of the most dangerous unprotected railroad crossings in Westchester county, New Jersey, Long Island and Staten Island. While the list is not intended to cover all the grade crossings in the vicinity of New York City, those not mentioned are so arranged that motorists have an unobstructed view of the track and by the use of ordinary caution can avoid accident.

Following is the list of the points where extra care is necessary:

Westchester County.

Just south of Briarcliff village, on the Putnam branch of the New York Central.

On Lake Mahopac road, ust south of Kitchawan, on the New York Central.

At Hawthorne, on the Harlem branch of the New York Central.

At Mill Plains, on the New York, New Haven & Hartford.

Two crossings between Mill Plains and Danbury, on the same railroad.

Long Island.

At Glenhead, on the Long Island Railroad. (A man was killed there a few weeks ago.)

At Westbury. (The automobilist, Fournier, and three men, one an official of the Long Island Railroad, were injured there a few weeks ago.)

At Rockville Centre.

Two crossings near Oakdale.

At Center Moriches. (A serious accident occurred there about six months ago.)

Between Jericho and Woodbury, on the Long Island Railroad.

At Sayville, near the railroad station, where the tracks cross the Cross Island Roadway.

New Jersey.

Two crossings at Bogota, on the New York, Susquehanna & Western and the West Shore railroads. (At this crossing Donald Holmes, a Paterson lawyer, was killed last Sunday. Shaw, the chauffeur, was fatally injured, dying on Tuesday. Two others badly hurt.)

At Leonia, on the Northern Railroad of New Jersey.

Near Closter, on the Northern Railroad of New Jersey.

Between Mattawan and Freehold, at Wickatunk, on the Central Railroad of New Jersey.

Between Freehold and Farmingdale, on the Pennsylvania Railroad.

Between Farmingdale and Lakewood, on the Central Railroad of New Jersey.

At Keyport, on the New York & Long Branch Railroad.

Staten Island.

Near Huguenot, on the Staten Island Railroad.

Near Giffords, on the Staten Island Railroad.

JERSEY'S GOOD ROADS MOVEMENT

Definite Plans for Convention at Atlantic City—Governor Fort and Leading Experts on List of Speakers.

At a recent meeting of the Associated Automobile Clubs of New Jersey, definite plans were adopted for a good roads convention to be held in Atlantic City on Friday and Saturday, September 25th and 26th. Efforts to interest the State Grangers in the affair have been successful, and the Associated Clubs propose to get in touch with every automobile club in the State and induce the different organizations to send delegates so that every locality will be represented. Aside from the regular organizations, the farmers, motorcyclists, and all others who are interested in the good roads movement, will be invited, and the road problem thoroughly discussed.

Not only have all the motor organizations in the State, including prominent members of the dealers' association, approved the plan, but State officials as well have set their seal of acceptance upon it. Governor J. Franklin Fort will make the opening address at the convention. Other speakers will be government experts from the Department of Agriculture at Washington and road experts from this and other States.

Individual members of the State Grange have showed a marked interest in the convention and an effort will be made to get the official support of the farmers' organization. Little trouble is anticipated along this line, for the reason that the convention is called as much to consider the farmers' interest as those of the other users of the highways, and the head of the National Grange promised the support of his organization to the good roads movement at the National Good Roads convention held in Buffalo recently.

The Atlantic City gathering will follow closely the lines of the recent Buffalo convention, with the exception that it will be local, and not national, in character, and so will be better equipped to take up the problems peculiar to New Jersey and its hundreds of miles of stone roads, that are famous all over the country and are constantly attracting an immense automobile traffic from other parts of the country.

New Attack on Anti-Trap Pickets.

"Doing unnecessary work on the Lord's Day," was the singular charge against a young man named Howard Hatch, who was arrested for standing in the vicinity of a "trap" in Norwood, Mass., and handing to automobilists a card warning them to keep within the limit of speed. The case was heard by Judge Hutchinson and the young man was convicted, but the case was placed on file. Judge Hutchinson, before finding the young man guilty, suggested that the Automobile Association, instead of having a man stand near the traps, should station one at either end of the town on the main road, and there hand out the cards. Chief Sackett also made the suggestion that a large sign be placed at either end of the town warning automobilists in regard to the speed limit. The case was put on file, with the hope that the town and the Automobile Association will agree on some plan so that they can work together in the future.

Automobile Emergency Repair Wagons.

Automobiles are to become a part of the equipment of the Brooklyn Rapid Transit, replacing the horse drawn emergency repair trucks that are a familiar sight to regular travelers over the many lines of street cars in the big Long Island borough of New York City. Demands for the emergency service have been hard on the horses which frequently have scarcely time to return from one long journey before there is a call from another direction. The possibilities of an automobile service appeared so inviting that it was determined to equip an antomobile truck of high power with the body and tower of one of the horse-drawn repair wagons and the results were satisfactory. The next step was to obtain a specially constructed gasolene vehicle of high speed and it now is in service. It carries an extension tower which enables the crew to work in ease and with safety on the overhead wires. In the body of the wagon, are the tools, repair kits and materials ready for instant use. Not only is it more rapidly and readily driven through the streets, but it is ready to answer with unflagging promptness any number of calls made upon it. The substitution of similar vehicles for the old style equipment now appears to be simply a question of time. Such a machine has been in use in England for some little time, and is reported as having given good service.

Atlantic City Forbids Warning Signs.

Warning signs placed by the Atlantic City Automobile Club along the roads in that vicinity are to be removed by order of the Board of Freeholders. The meeting, held on Wednesday, 5th inst., was marked by excitement. The signs to which objection is made read "Slow to legal limit; police trap." Mr. Irving, a freeholder who represents the district in which John Carver, the Judge who last month collected $400 in fines from those who ran through the village faster than 20 miles an hour, is located, demanded that the signs be torn down.

"As soon as they pass these warnings, he said, "they drive recklessly and dangerously, and the signs are an outrage upon justice. It looks to me as though the club is not in sympathy with having the speed law obeyed, but is trying to save the automobilists from being fined for their lawbreaking. I believe in Justice Carver's rigid enforcement of the speed regulation."

TEST FOR ANTI-SMOKE ORDINANCE

Cab Company Assails Constitutionality of Park Board's Law—Appeal from Judgment Against a Chauffeur.

In order to test the constitutionality of the new anti-smoke ordinance of the New York City park board, William Scully, a chauffeur employed by the New York Taxicab Co., was arraigned before Magistrate Moss in the Yorkville police court on the 5th inst., charged with permitting smoke to issue from the exhaust vent of his machine He was fined $2. Louis D. Mooney, counsel for the company, said he would pay the fine under protest, and would appeal the case at once to test the constitutionality of the ordinance. Six other chauffeurs of the company who had been arrested were discharged.

At the invitation of Magistrate Moss Assistant Corporation Counsel George Nickerson and Mr. Mooney were present to listen to the testimony against the chauffeurs, and it was decided to make a test case, Scully being selected as the defendant. It was ordered that copies of the minutes of the hearing be furnished Messrs. Nickerson and Mooney.

Philadelphia Persists in Its Shakedown.

Nearly 3,000 owners of automobiles in Philadelphia have all season long operated machines with State permits only, regardless of the fact that an additional city license is required, and in order to put a stop to this evasion of the law the Department of Public Safety will in the near future issue a circular letter calling for attention to the fact that a city license is just as necessary as a State license. The cost of a city license is $2 per year for the original license and $1 for each year in the future. Owners and operators of automobiles have all along contended that a State license is sufficient, but the local authorities will in the future enforce the ordinance.

Jersey Justice Pursues a Phantom Car.

Frederick C. Eberlin, manager of the Stock Exchange power plant, received the following official letter on Saturday last, 8th inst.:

Ancora, Camden,
"8—5—08.

"Dear Sir—While speeding your machine 3530 on July 11, 08, on the County Road between Berlin and Hammonton, my Officer found You exceeding the Speed Limit; machine running at the Rate of 63 seconds to ½ Mile; therefore accountable to a fine of $25 and $5 cost. Not wishing to take Lawfull action, I await your reply. Yours truly, C. WALDROGEL, J. P., Ancora."

Not having owned or driven a machine for four years, Mr. Eberlin naturally believes that he can prove a perfect alibi and C. Waldrogel, J. P., undertakes to enforce the Jersey law on him.

EXHAUST GAS AS A GERMICIDE

London Physician Says the Automobile Smell Combats Disease—Chicago Doctors Ridicule the Assertion.

Right on top of all the fuss about obnoxious exhaust from automobiles, which is causing numerous arrests in New York, comes the information of a certain London scientist claiming that exploded gases coming from the muffler kill germs and thus greatly lessen the possibility of disease contagion. American scientists and physicians, however, do not agree with their English colleague, asserting that no such thing occurs, in spite of the fact that the death-rate in London is less at present than it has been in 50 years. From which, it is obviously to be doubted if we will ever disinfect our houses or fumigate them after sickness, by attaching a hose to the muffler of our car and permitting the engine to pump smoke and lifeless gases into homes. Dr. J. F. Biehn and Health Commissioner W. A. Evans, declare that the anonymous London physician who says "the burnt carbonized matter is a splendid antiseptic and the creosote vapors that come from the motor are in reality a health tonic and bracer," had reason to seclude his name.

"All the creosote deposits from all the automobiles in Chicago," said Dr. Biehn, "wouldn't kill the germs on a square inch of city pavement. If the machine is a good one there is nothing left from the combustion of the gasolene except carbonic acid gas and water. In any event there could be no great amount of substances of an antiseptic nature. The Londoner was dreaming."

Dr. Evans' position was that the gases had absolutely no purifying effect upon the atmosphere.

"Germs are hardy things, as anybody knows," he explained. " A germ can stand anything that a man can, and I haven't heard that automobiles had caused any deaths recently in that manner. When one wants to fumigate a room the fumes of the sulphur or formalin must be so strong that a man can't stand them, or the germs 'live happily ever after.'

"I wouldn't say that the automobile gases are especially harmful. I should call them merely objectionable."

Inexpensiveness of Swiss Motoring.

Though Switzerland has commonly been regarded as a country where travelers are looked upon by inn keepers and the law makers as legitimate prey, the amount of $2.59 per day per person, the cost recorded in the case of a recent experience is by no means a sum to worry over. According to Dr. A. H. Heaton, of the Missouri Automobile Club, this amount represents his average expenditures for a trip which he now is taking through European countries. In his itemized accounts of one week in Switzerland, Dr. Heaton records hotel bills at $22.10; gasolene, $8.90; cleaning, garage, laundry and sundries, $5.30, making a total for two people of $36.30, or $18.15 for one.

For 13 consecutive days, June 14th to 26th, and including the cost of shipping the car across the Channel on its return to England, the total for two persons was $86.71, or $43.35½ per person, making a daily average of $3.25 per person—the very necessary item of tips, included. Dr. Heaton's original estimate of the daily cost per person was $4.68, the conservatism of which is emphasized by the statement that his average has not reached $4 per day at any time during the trip.

Teamsters Want Union with Chauffeurs.

Believing that the perpetuity of their organization may in time depend upon affiliation with the drivers of motor cars, the United Teamsters of America are seeking to have the Chauffeurs Protective Association of America join with them in the formation of a mutual alliance. This fact developed through discussions carried on at the national convention of the Teamsters which was held in Chicago on August 3d. The delegates to the convention represented 75,000 teamsters, located in all parts of the United States, and prominent in this gathering was Albert Oliver, who appeared as representative of the Chauffeurs Protective Association. Oliver is the first representative of an organized chauffeurs' union to be seated in a teamsters' convention.

Mount Wachusett Open to Automobiles.

By grace of the State reservation commission of Massachusetts, automobiles now may go to the summit of Mount Wachusett, provided the trip is made between the hours of 12 and 2 p. m. or 5 and 7 p. m. Automobile parties desiring to remain on the summit over night can obtain special permits to descend in the forenoon. Mount Wachusett is one of the most conspicuous protuberances on the geographical face of the Staee, not because of its height but because of its lone position. Because of this fact and the comparative ease with which it can be ascended it is a delightful spot for tourists to visit, affording views as varied and beautiful as they are far extending. It is a State reservation.

Pittsburg Frowns on "Joy Riding."

Automobile owners of Pittsburg, Pa., are going to try to take concerted action to prevent "joy riding," the first instance of mutual interest being shown in the Allegheny county court last Thursday when Harry Curtis, a chauffeur, was put on trial charged with trespass, it being alleged that he took the automobile of his employer and gathering a party went out and got drunk and ran the automobile into a ditch. Several automobile owners have agreed to divide the expense of this case.

FARMERS DEMAND BETTER ROADS

Rural Free Delivery and the Automobile Awaken Indiana Agriculturists—Pushing Highway Improvement.

That the development of the rural free delivery is going to play an important part in the good roads movement is shown by the activity of the government in response to the insistent demands of Indiana farmers for better roads in that State.

Before the advent of rural free delivery of mail the farmer was more or less indifferent about the condition of the roads, but in the last few years he has been buying automobiles and has grown accustomed to the luxury of having his mail delivered almost to his front door, and now he demands that better facilities be afforded him for the use of his motor car and to insure a consistent following of the mail schedule.

In response to this situation, the Post Office Department of the government is doing more in Indiana to extend good roads work than is being done through the combined efforts of all the good roads associations. This year's estimates of $8,000,000 for the building of roads in the State probably will be insufficient as the amount of work in hand will require much more than that sum to insure its completion. Recently the government, through its postal authorities, has been vigorously demanding that the roads shall be improved still more.

In the vicinity of Charlestown the entire rural mail service threatens to be discontinued, because of bad roads, and farmers are now projecting the building of 41 new roads. In other parts of the State officials and business men are hurrying through road improvements to save rural routes. Madison county is preparing to build 21 new roads at a cost of $250,000. The South Bend Business Men's Association is making special efforts in the direction of having good roads built.

Massachusetts to Issue Special Licenses.

Restricted licenses for non-resident operators are to be issued by the Massachusetts Highway Commission for the benefit of those who wish to run their cars into the State without being held up. Many such operators have been of the sort fully competent to take out a license, who have merely needed the right to operate until they could get their cars to some point where they could meet the commission's examiner and satisfy him of their fitness. The commission, under the law allowing it to place restrictions on licenses, has now decided to issue certain licenses in response to application by mail, the license to become void unless the operator passes a Massachusetts examiner before the end of the stated number of days, as set forth in the preliminary certificate.

NORWAY HAS FEW AUTOMOBILES

American Consul Suggests that Present Limited Demand Might be Increased—One Native Factory Operating.

Norway probably would scarcely be regarded as a likely field for automobile exploitation. Nevertheless Vice-Consul-General Michael Alger, of Christiania, explains that a certain limited demand already has been built up, and indicates that it may be extended under proper conditions, which may follow later on. Of the 87 machines in present use in the country, the majority are to be found at Christiania—the only place where registrations may be recorded. These registrations come under the jurisdiction of the police department—29 of the present total having been received during the year 1907.

"Most of these are used for purposes of pleasure, but a few delivery cars are in use," he says. "All of these automobiles have been imported; about 25 are of American origin; the others are of French, English, and German manufacture. A few large machines of 35 to 40 horsepower have been imported, but most of the automobiles in Norway are of the smaller kind.

"There is only one automobile factory in Norway, and its output so far has been limited to two small cars. The competition offered by domestic manufacturers is therefore of no consequence. The Norwegian import duty on motor cars is 12 per cent. ad valorem.

"The kind of automobiles most likely to find a market here will be those ranging in price from $900 to $1,500, about 20 horsepower and well equipped to climb steep grades. Larger machines at higher prices will find but few buyers, inasmuch as there is only a small number of persons in Norway who can afford the luxury of expensive automobiles.

"The intended utilization of motor cars for conveying passengers as well as goods in several country districts, especially along the most frequented tourist routes, offers a field for sale of automobiles in Norway. Such traffic is now carried on by horse vehicles. In the district of Osterdalen, the principal valley of the country, several such automobile routes are now under contemplation. Likewise in the Trondhjem district, between the town of Stenkjar and Rodhammer, and in the Telemarken district, between Notodden and Sauland, automobile routes are to be opened.

"Automobiles intended for the Norwegian market should be equipped with double tires—that is, with inner air tube and outer casing, which latter should always be provided with an outside metal cover for protection against the sharp crushed stone used in the paving of many of the roads; otherwise punctures will occur too frequently.

"All chauffeurs must demonstrate their ability before they can obtain a license from the authorities to drive a car. Of such qualified drivers there are 121, 47 of whom were registered in 1907.

"The strict rules and regulations laid down by the authorities for driving automobiles on the Norwegian highways continue to be a serious drawback to the development of the use of motor cars in this country. Every district has its special rules in regard to such matters; thus a new permit has to be obtained for each one to be traversed. In some districts automobile driving has been entirely prohibited; in other places only certain roads within the same district may be used, and then on certain days and at specified hours only. The explanation given is that the roads are too narrow for the safe passage of horse vehicles and motor cars at the same time. It should be remembered that some of the Norwegian public roads have a width of about 7½ feet only, and that they have many sharp curves.

"New and more liberal rules, uniform for the whole country, as far as practicable, in regard to this matter, are now under preparation by a committee specially appointed for the purpose; but it will still take a year or more before any new enactment will come into force, and until then the automobile trade must reckon with the rules of the present.

"American automobiles have been well received here, and their many good points have been duly appreciated, but it seems that they range too high in price compared with English makes. Thus a British firm offers a 30 horsepower, 6-cylinder machine for $2,626, while an American 20 to 25 horsepower motor car costs $2,814. The terms of payment are always in favor of the European manufacturer, who generally gives long credit to solid purchasers, while the American invariably demands cash on delivery, or at least against shipping documents here."

Passenger Lines for Ohio Towns.

Warren, Ohio, and Cortland, in the same State, are to be connected by an automobile passenger line. The Cortland Transfer Co. has been incorporated and very shortly will operate a passenger, freight, express and possibly mail service between the two places. There is but one train each day between these towns and not only do residents experience considerable difficulty in getting to and from work, but the mail service is very poor.

Orders Automobile Fire Engines.

Lansing, Mich., has ordered an automobile fire engine. The machine is to be of sixty horsepower and designed to carry six men and equipment. Specifications call for a pumping capacity of 600 gallons per minute at a pressure of 180 pounds per square inch. The price of the machine will be $6,000.

OPERATORS MUST FILE PHOTOS

Roundabout Process of Obtaining Automobile Licenses in Mexico—Extortion in the Form of Fees and Taxes.

Getting an automobile license in Mexico is a matter of circumlocution. At the outset the owner of a machine must make application to the Governor of the Federal District for examination as to his capability for operating it. The application, written on regular official paper, having a wide margin on the left hand side, must give the applicant's name and address together with a description and the number of the machine. The application is presented in person, between the hours of 9 and 11 a. m., to Senor Pedro Buch, at 2a Ribera Santa Maria, No. 1128, and if satisfied as to the capability of the applicant, Mr. Buch will endorse the paper favorably, assigning thereon the number allotted to the machine.

The paper then must be presented to Seccion la del Go. del Do. between the hours of 11.30 a. m. and 1 p. m., or 4.30 and 6 p. m., together with two photos of the applicant each measuring 5x4 centimeters. Two document stamps, one for 50 cents and another for 10 cents, must be presented at the same time for attaching to the "Certificate of Aptitud" and "Permit to use automobile" respectively.

These certificates are then granted, together with the numbered plate for which a charge of $3 is made. The plate must be taken to the office of Mr. Buch so that it may be attached to the automobile. As a rule two days are required from the time application is first made to the final placing of the number.

In the same building at which the certificates above mentioned are granted, a bimonthly tax, at the rate of $2 per seat, per month, must be paid. Thus the tax for an automobile seating five people would be $20 every two months. The licensed owner receives a voucher, also written on official paper, giving the date of the granting of his certificate of aptitude, the number of such certificate and the address at which the automobile is kept. In renewing the payment of his tax he must show the receipt issued for the last previous payment.

Meriden Wants a Police Patrol Wagon.

Meriden, Conn., joins the cities adding automobile equipment to the facilities of municipal departments. Chief Bowen, of the Police Department, has been instructed to inquire about prices of police patrol vehicles and prepare an estimate to be submitted by the police board to the city council with the estimates for next year's appropriation. The police headquarters already is provided with a station for an automobile, that having been included in the plans for the building now occupied.

The Week's Patents.

888,737. Automobile Running Gear. Charles T. Pratt, Frankfort, N. Y. Filed Jan. 24, 1907. Serial No. 353,890.

1. The combination in an automobile running gear of a pair of forward steerable wheels secured by pivotal joints to the ends of an axle and carrying the forward end, a truck consisting of an intermediate pair of steerable wheels secured by pivotal joints on the ends of an intermediate axle and a pair of non-steerable wheels secured to the ends of the rear axle and half elliptical springs extending longitudinally of the running gear on each side and secured to the intermediate and rear axle at their respective ends and means for supporting the rear of the body from said truck engaging on the middle portion of said springs respectively, substantially as set forth.

888,794. Starting Means for Gas Engines. David Ferguson, Buffalo, N. Y., assignor to George N. Pierce Company, Buffalo, N. Y. Filed May 8, 1906. Serial No. 315,787.

1. The combination with an engine having a relief valve, of a rotatable operating device for said relief valve which is driven by the engine and is normally in an inoperative relation to said relief valve, means for starting the engine, and a device which is connected to said starting means and is moved thereby transversely with respect to said operating device for moving the same axially into operative relation to said relief valve, substantially as set forth.

888,823. Vehicle Tire. Harry A. Knox, Springfield, Mass. Filed Dec. 13, 1905. Serial No. 291,623.

1. In a vehicle wheel, the combination with the rim thereof, a channel iron secured thereto, a series of springs extending transversely of said channel iron, said springs being so placed as to form a space between one spring and the next, and a series of holes through the flanges of said channel iron and located between said springs, and means for securing said springs to the channel iron.

890,083. Ratchet Coupling. Thomas W. Morgan, Waterloo, Iowa, assignor to Wilbur W. Marsh, Waterloo, Iowa. Filed May 11, 1907. Serial No. 373,183.

In combination, a shaft having a toothed outer race and having an outwardly projecting spindle, a band wheel rotatably seated on said spindle and provided with a bearing hole on its inner side, the outer side of said band wheel having a hub provided on its outer face with teeth, a compression spring in said bearing hole, a slidable pin in said bearing hole upon said spring, said pin adapted to engage a tooth on the outer face of said shaft when said band wheel is rotated in one direction, and be disengaged therefrom when rotated in the reverse direction, a crank having a hub rotatably seated on said spindle and such hub having a bearing hole in its inner face, a compression spring seated in said bearing hole and a slidable pin seated in said hole upon said spring, said pin adapted to engage a tooth on said band wheel hub when the crank is rotated in one direction and to disengage therefrom when the crank's rotation is arrested.

890,099. Carburetter. Henry Richardson, Waltham, Mass. Filed March 16, 1907. Serial No. 362,719.

1. In a carburetter the combination of an automatically closing valve and an elastically mounted adjustable stop therefor, limiting the opening of the valve, said stop being at a distance from the closed position and engaging the valve only when the valve is open.

890,107. Power Transmission Mechanism. Bennett Van Decar, Syracuse, N. Y. Filed June 25, 1906. Serial No. 323,290.

1. In a power transmitting mechanism, an epicyclic train having two separately revoluble planetary wheels traveling in different concentric deferents, one deriving rotary motion from the other.

890,247. Igniting Mechanism for Internal Combustion Engines. Clarence A. Myers, Frederick W. Haas, Jr., and Alvah A.

DOW TUBES Are the Most Economical

(The Best Tubes Ever Manufactured)

ONE YEAR'S CONSTANT SERVICE IN THE BOSTON FIRE DEPARTMENT

Dow Tire Co., New York, N. Y. Headquarters Fire Department, City of Boston, Bristol Street, Boston, July 20, 1908.

Gentlemen—Having used the Dow Non-Deflation Tubes since August 19, 1907, on the automobile used by Chief Mullen of this city fire department in his response to alarms of fire, I feel that, in return for the excellent results received from these tubes, I ought to inform you of same. Several persons have inquired of me as to their merits, and I have always spoken in the highest terms of them, but never felt that I could write you confirming my statements until such time as they had been in use for about a year.

We have given them all kinds of tests, and will truthfully say that they have withstood all punctures, and with the exception of "blowouts," which are liable to occur with any type of inner tube, they have given excellent satisfaction.

Trusting this letter may be of benefit to you, I remain, Yours very truly, (Signed) JOSEPH A. WEBBER, Lieut., Aide to Chief.

Digitized by Google

Myers, Chicago, Ill. Filed March 7, 1908. Serial No. 419,794.

1. In a sparking apparatus for internal combustion engines, the combination with a plug having a threaded body, of electrode shafts journaled in said body to have oscillatory and rotary movements, rotary and oscillatory electrodes carried by said shafts, a driving connection for rotating one of said shafts, a spring carried by the outer end of the oscillatory shaft for holding the electrode advanced with a yielding pressure, a cap inclosing the outer end of the plug, and a packing gland through which the rotary shaft projects from the cap, substantially as described.

890,362. Tire Protecting Deviee. Leonard H. Kinnard, Harrisburg, Pa., assignor of one-half to Rollin S. Chamberlin, Harrisburg, Pa. Filed Nov. 14, 1904. Serial No. 232,554. Renewed July 6, 1907. Serial No. 382,473.

1. A tire protecting device comprising a stiff annular shield whose internal diameter at each edge is less than the external diameter of the tire inflated, and which normally makes contact along its edges with both sides of the tire and between its edges with the outermost portion of the tire, and whose internal surface recedes from the tire on each side of the innermost portion of the shield, the stiff material of the shield increasing in thicknes from the edges to the outermost portion of the shield.

890,473. Vehicle Steering Device. Edward J. Vraalstad, Buffalo, N. Y. Filed April 19, 1907. Serial No. 369,081.

1. In a steering gear for vehicles, the combination with a steering rod, and a duplex male screw thread thereon, of two interiorly threaded nuts, one for each thread, one nut being telescoped by an extension of the other nut, and a swinging member by said nuts.

890,482. Circuit Closer and Breaker. Alexander Winton, Cleveland, Ohio. Filed Sept. 15, 1904, Serial No. 224,584. Renewed March 12, 1908. Serial No. 420,695.

1. An explosive engine ignition system including an annular non-conducting contact running surface, an electrical contact depressed therein and flush therewith, the non-conducting running surface cut away at the side of the contact for the purpose described, and a roller contact spring held against and rolling on said running surface, whereby the roller contact travels smoothly across said cut away portion.

890,494. Carburetter. Orra E. Byron, San Francisco, Cal. Filed Aug. 13, 1907. Serial No. 388,301.

1. In a carburetter, the combination of a member provided with ports through which air can pass, and a valve member provided with portions for successively uncovering said ports so as to permit the passage therethrough of varying quantities of air, and a vacuum controlled diaphragm connected with said valve member for actuating the same.

890.532. Explosive Engine. Alfred P. Schmucker, Denver, Colo. Filed Jan. 14, 1905. Serial No. 241,119.

1. In an explosive engine, the combination of a common crank chamber, a charge inlet therefor, a number of cylinders connected therewith, each cylinder having an auxiliary chamber provided with two ports communicating with the cylinder, one port being at the inner extremity of the cylinder and the other in position to be uncovered when the piston is at its inward limit of movement, for the escape of the explosive mixture into the outer extremity of the cylinder, the said mixture having been compressed in the auxiliary chamber during the inward movement of the piston.

SOLARCLIPSE LAMPS

Suppress Your Powerful Headlights
when you drive your car in the City.

SOLARCLIPSE MOTOR LAMPS

make this possible.

Through the Patented Besnard System of light eclipsing the powerful long distance ray may be suppressed at will through the automatic eclipsing mechanism which operates from the dash.

Solarclipse Lamps throw two distinct rays. One long distance which penetrates the darkness for over 1,000 feet ahead—the other short distance which is thrown directly in front of the car. The driver at all times controls the lights, as he controls the operation of the car. Solarclipse Lamps scientifically solve the lighting problem. See that your car is so equipped.

Warner Auto-Meter

GUARANTEED FOR ONE YEAR.

"Thirty Days' Free Trial"

When a manufacturer is willing to send his product to anyone, anywhere, for 30 days—with no deposit, no agreement to buy, no promise to do anything except give that product a fair trial—he must have more than ordinary confidence in his article. In order for him to have that confidence he must have a most extraordinary product.

That's what we do. We'll send an Auto-Meter to any automobile owner in the country—with no deposit, no agreement, no promise to do anything but put it on his car and give it a fair trial. It doesn't matter whether he has another make of speed indicator already on the car or not. Indeed, for the sake of comparison, we hope he has. We will abide by the decision—for he will always keep the indicator that tells the truth. We claim for the Auto-Meter that it is the only one of which "the dial never lies." We believe that the instrument itself is the most eloquent salesman we have—we're willing to let it do our talking. Send to-day—just tell us what make and model of car you have—size of tires, etc.—and we will send you an Auto-Meter.

WINTON SIX

Goes the Route Like Coasting Down Hill

This 48.6 horsepower, five-passenger Winton Six at $3000 represents the most profitable investment offered to you by motor car makers—

BECAUSE

—it gives more power than any other car at anything like the price.

—it has a six-cylinder motor—the accepted high-grade type. If you have never ridden behind a real six-cylinder motor, you have the pleasantest surprise of your automobile experience awaiting you. Try the Winton Six and observe its superiority is quietness, smooth-running, flexibility (which means any speed you want on high gear), hill-climbing, comfort, and all-around enjoyment.

—it has a mechanically-infallible self-starter, that eliminates cranking.

—its upkeep expense is the lowest of first-class cars. Proved records of 65,687.4 miles (more than twice around the world) show upkeep expense of $1 for each 4343 miles.

—it is the same car in every mechanical feature that we made this last season and is therefore a proved car in every detail—a car without an experimental feature—no skimping in weight, quality of materials or character of workmanship.

For great power and seven-passenger body, see the 60 horsepower Winton Six, with four-speed transmission, at $4500.

Own a Winton Six and you own the best there is.

Write to-day for literature: 1—Winton Six catalog; throws new light on Sixes. 2—"One Dollar Upkeep for 4,343 Miles" booklet; a record of sworn testimony, not hearsay. 3—"Another $2,500 for Ten Good Chauffeurs" booklet; details a plan to benefit owners.

THE WINTON MOTOR CARRIAGE CO., *Member A. L. A. M.* Cleveland, O., U. S. A.

ARE YOU TIRE-TIRED—in the sense that you are weary of buying your tires in the grab-bag, hit-or-miss sort of fashion, where you take all the chances and pay all expenses, getting 1,000 miles out of one tire and maybe 4,000 out of another?

THE CHANCES ARE that you do not know of the Ajax 5,000 Mile Tire Guarantee—a guarantee that guarantees—or, if you were, you considered it too good to be true.

THE AJAX 5,000 MILE GUARANTEE absolutely eliminates your tire hazard, enables you to figure out your whole tire expense in advance with unfailing correctness.

TO RIDE ON AJAX TIRES COSTS SO MUCH and no more. If your tire does not come up to the mark, we make good the written guarantee that goes with every tire sold.

THERE IS NO GAMBLE—NO "IF"—we do the worrying for you. In the light of the quality of Ajax Wrapped Tread Tires we can well afford to offer and execute our 5,000 Mile Guarantee.

Write for copy of Guarantee, stating what size tire you are using.

BEAR IN MIND

that in eight years there have been five models of Stevens-Duryea Cars. Worked out to perfection before being placed on the market—their mechanical features distinguished for being ahead of the times and because of common sense construction. Contrast the evolution of five unqualifiedly successful Stevens-Duryea Models with the every few months "improvement," radical changes, etc., in the output of some motor factories.

WHEN YOU BUY A STEVENS-DURYEA CAR YOU SECURE A MINIMUM OF UPKEEP EXPENSE AND A MAXIMUM OF PEACE OF MIND.

AT LAST THE GREAT PROBLEMS OF WEIGHT, VIBRATION, NOISE AND ECONOMY ARE SOLVED

A Six-Cylinder Thomas Flyer

Six-Passenger Car
Forty Horse-power

for $3,000

Five to Fifty Miles
Per Hour on High Gear

One thousand pounds of crude and useless material eliminated. The average automobile weighs five or six times its passenger capacity. The 6-40 Thomas Flyer weighs but little more than twice its passenger capacity, reducing the cost of tires, operation and maintenance one half.

A CAR WITHOUT A NOISE, JAR OR VIBRATION.

The greatest improvement in years—a distinct and marked advance which will create a new era in automobiles, which engineers have long known must come.

AN IDEAL FAMILY CAR

Extremely artistic and refined. One to be proud of for its beauty, style and luxury, and to love for its extraordinary silence, smoothness and sweet running and easy riding on rough roads, in which it greatly excels, and which, taken as a whole, comes nearer fulfilling all requirements for family use than any car hitherto made, except those requiring extreme speed, power and size.

THERE IS NOT AN EXPERIMENTAL FEATURE IN ITS WHOLE MAKEUP

The wonderful results are due to severe simplicity and compactness of design; new arrangement of functional parts; six-cylinder constant torque; the very best quality of nickel, vanadium and heat-treated steels, which are lighter and stronger; and the frictionless features of annular ball bearing cam-shafts, crank-shafts, transmission and wheels, and the highest quality of workmanship, which delivers the highest efficiency to the rear wheels.

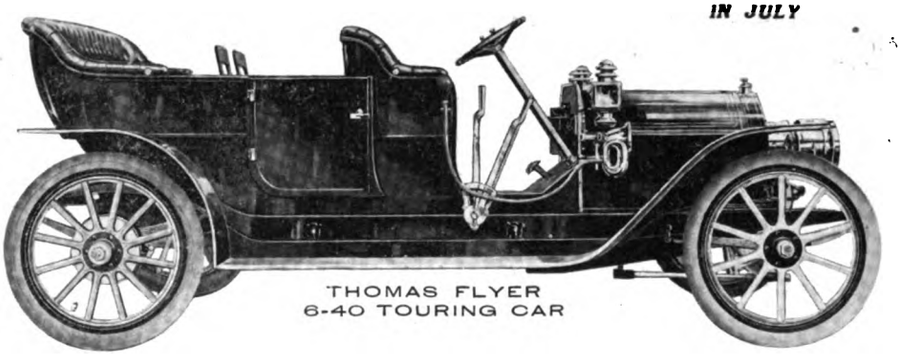
WEIGHS ONLY 2,000 POUNDS

Features of Thomas 6-40 Flyer

In no sense is the 6-40 Thomas Flyer a cheap car: it is the other extreme.

In addition to the great advantage of ball-bearing, six-cylinder construction, it includes the most expensive features conducive to reliability and comfort, which are usually found only on $6,000 cars.

Two entirely separate and distinct ignition systems; Sims-Bosch magneto and Atwater-Kent timer for easy starting and reserve ignition; two sets of spark plugs.



36-inch wheels and tires; low center of gravity.

3-disc clutch, encased in oil; patented.

Double Elliptic springs.

122-inch wheel base.

ALL SHIPMENTS START IN JULY

THOMAS FLYER
6-40 TOURING CAR

Gas and oil lamps.

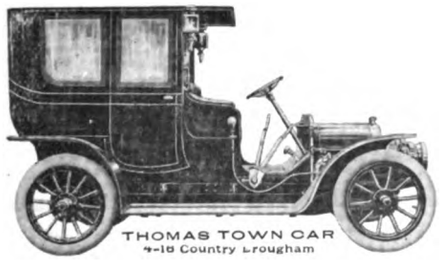
Prestolite tank.

Hand-hammered aluminum body; seats six looking forward, most beautiful and luxuriously upholstered and finished.

Body practically suspended between axles—the modern style.

Transmission on floating type rear axle.

Drop frame. Herringbone gears for quietness.



18-inch steering wheel; ball-bearing knuckle, exceedingly easy to steer.

Fan on fly-wheel. Four brakes. Three-point motor suspension; aluminum hoods and fenders; geared lubricator.

Touring Car, Flyabout, Tourabout, $3,000.00.

Limousine, $4,500.00.

OTHER 1909 THOMAS FLYERS

THOMAS TOWN CAR
4-16 Country Brougham

THOMAS FLYER
4-60 Touring Car

THOMAS FLYER
6-70 Touring Car

A CAR FOR EVERY DAY IN THE YEAR.

Winter or summer; night or day; rain or shine. Warm in cold weather. Cool in hot weather. Dry in wet weather. Closed if dressed for shopping, theater or social functions; open to the sunshine and breeze when touring.

It has a speed on high gear from five to forty miles an hour and will negotiate any passable hill or road. It will carry its people quietly, smoothly and luxuriously. It's the safest car in the crowded city streets or on a suburban road.

Owing to its short wheel base it will turn in an ordinary street without backing. It will not skid on slippery streets and owing to its low center of gravity rides smoothly without rocking. Its wide doors and low step permit of very easy ingress or egress.

TO THE OWNERS OF LARGE TOURING CARS:

This car will be used two-thirds of the year for business, shopping, theater and social functions, for which the open car is not adapted, saving more than half the expense of operation and cost of maintenance and tire renewal of a large car.

Should you live in the country it will carry you more exclusively, quietly and comfortably than a railway or street car. It fulfills any business or social requirements. It is a car that is well worth your investigation.

Country Brougham, Landaulet and Cabriolet (f.o.b. Buffalo), $3,000.

The Old Reliable Thomas Flyer—Ready For a Trip Around the World at any Minute.

Mechanically a duplicate of the stock car selected only six days before starting, without special preparation or test for the great New York-Paris Race. Won the international endurance race to San Francisco, and at this writing is still ahead. The only car that went the route; and the winner of more contests than any model in the world. Plenty of reserve power, reserve strength, reserve speed, roomy, luxurious, quiet, well balanced, splendidly proportioned.

Two separate and distinct systems of ignition. Back stop and safety device, easy riding; four very large brakes. Thomas three disc clutch patented. Four speeds forward and reverse. Easy steering.

This is practically the third year for Model F. Each year a little smoother, a little faster, more refined, more luxurious.

Touring Car, Flyabout, Tourabout (f.o.b. Buffalo), $4,500.00.

Limousine, Landaulet (f.o.b. Buffalo), $6,000.00.

THE MOST POWERFUL, COMPLETE AND LUXURIOUS STOCK CAR MADE.

The very climax of automobile construction. Equipped with top, speedometer, clock, prestolite tank, tire irons, two separate ignition systems, geared fans, oilers and pumps. Everything that money can buy.

Splendid body balance and exceedingly easy riding.

The greatest reserve of power, speed and strength with the constant torque of six cylinders, insures the smoothest running on high gear amidst the crowded streets or on muddy roads and steep hills.

The 1909 model will be faster, smoother and quieter than ever. The 6-70 Model K is the fastest stock car in the world. It eats up the hills on high speed easier than the average car takes smooth roads and excites an exultation, pleasure, contentment and pride not possible with any other car.

Touring Car, Flyabout, Tourabout (f.o.b. Buffalo), $6,000.00.

Limousine, Landaulet (f.o.b. Buffalo), $7,500.00.

Chalmers-Detroit "30"

"It's a Good Car"

A high-grade 4-cyl., 5-passenger, 24-30 h.-p. car, made by the makers of the Thomas-Detroit Forty.

1909 Models Ready

Touring Cars
Tourabouts
Roadsters

Price $1,500

Our Profit Nine Per Cent

No doubt other cars will be offered around this price. It remains for you to compare them.

Here is one so good that our profit—based on our full capacity of 2,500 cars—will be but nine per cent. Judge if anyone else gives so much for the money.

Here is one that has two years the start of all others. We have spent two years in perfecting it. It is not a makeshift—not an experiment.

This one has behind it all the reputation—all the skill and experience—we gained in making that incomparable car—the Thomas-Detroit Forty.

This one is designed by H. E. Coffin—for years the chief designer of the Thomas Companies—one of the leading automobile designers in America.

The car combines the best foreign features with the best American. For Mr. Coffin made two trips to Europe in working it out. Yet it copies nothing, either foreign or American. It simply adapts the best principles of the world's best engineers.

This car is not assembled from stock parts picked up haphazard. Every design of every part is made by our own engineers—the best engineers in the business. All the leading features are patented.

This car is luxurious—speedy and powerful—a car that you can take pride in. Low in price—economical in upkeep—yet with all the perfections of the costliest cars.

Compare it with rival cars—with any car costing up to $2,000. We are willing to abide by your judgment.

The first of these cars cost us $33,000. Then last winter, when things looked bluest, we contracted for $3,000,000 worth of materials—to save you 20 per cent.

That is how we made this car possible—by taking enormous risks. Yet we ask for our profit a paltry nine per cent.

Our 1909 cars are now being delivered.

Note These Facts, Too

The factory cost on this 4-cyl engine is $261. Yet 4-cyl. automobile engines are sold as low as $75.

The transmission costs us $94. The axles—made of Nickel Steel—cost us $125.

The annular ball bearings used in this car cost $103. We use as many as the Mercedes uses—the Hotchkiss or Renault.

Look at these costs again. Then think that they refer to features of a $1,500 car. We could save half or more on any of them were we trying to stint on this car.

We equip this car with Diamond QUICK DETACHABLE tires. The usual clincher tires would cost 15 per cent. less.

We authorized our factory to spend on the body finish 15 per cent. more than their estimate. Our crank shaft is larger than on any American car under 60 h. p. Our brakes are enormously strong.

Twice the price can buy no better features. It can only buy more power.

The same economy applies to extras and to replacements. We furnish one of the best tops for $100. A Simms-Bosch Magneto for $125. Two gas lamps and a gas tank for $50.

Our repair parts are all sold on a reasonable margin—not at the usual profit of 200 or 300 per cent.

The four cylinders are cast together, as in the latest Fiat, Mors, Argyll and Hotchkiss. This gives lightness, compactness, perfect alignment, and a dozen other advantages. The only argument ever advanced against it is "cost of replacement." We answer this by furnishing a set of four cylinders for $35, less than most makers charge for two or even for one cylinder.

We use the Unit Power Plant, as in the latest Decauville, the new Hispano-Suiza, and the Motobloc. Motor, clutch and transmission form a single unit, so they cannot get out of line.

The wheel base is long—110 inches—insuring easy riding. The body is suspended between the axles, after the style of the Mercedes.

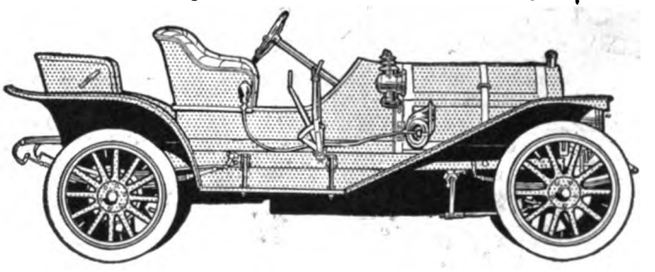
Valves like the new Napier. The ¾ elliptic springs like the Renault. Multiple disc clutch like the Isotta and Fiat.

The gas intake is water jacketed to avoid the troubles caused by cold gasoline. Constant level splash lubrication—perfect dust protection.

Floating type rear axle, used heretofore only on the costliest cars. Selective sliding gear transmission—three speeds and reverse. Anti-backing device to protect you on hills. Provision for double ignition system.

So simple in control that a novice can master the car in ten minutes. A single pedal operates both clutch and brake.

It is easy to claim the best car at the price. But compare the facts—put all claims to proof. We have no competition to fear.



It is also easy to criticize features that others can't afford—devices that others can't copy. But let us answer those criticisms and you will realize how weak and how futile they are.

At this writing it looks as if the demand for this car would be twice our supply. Orders are filled in turn, or you can reserve a car for future delivery.

Please act at once—send for our catalog now. For, when our output is taken, you can find no car within $500 of our price to compare with the Chalmers-Detroit "30." Don't wait and regret.

Chalmers-Detroit Forty

Formerly the Thomas-Detroit Forty

Chalmers-Detroit Forty Roadster, $2,750

The best guarantee that our $1,500 car has is the fact that it is made by the makers of the Chalmers-Detroit Forty.

This car is incomparable. We have never been able to make enough of them to supply the demand. Our output every year is sold before June, and this year (1908) we could have sold 200 more.

The 1909 models of the Forty—now ready—are the same as the 1908 models, save for the brakes and the springs. The brakes are heavier, the springs more easy riding. We know no way to improve it. The records it made during the past two seasons prove it the best medium-priced car that is made. Its users seek for nothing better.

We advertise our Forty in but a limited way. Our present users, through their endorsements, more than sell our output. The only way to get one is to order early.

The 1909 models of the Chalmers-Detroit Forty are shown in our catalog. Made in two styles—Touring Car and Runabout. Price $2,750.

This change in name involves no change in ownership, personnel or management. It is simply made to avoid the confusion of two Thomas concerns operating on separate lines.

THE BRAMPTON MOTOR CHAIN

All side plates on both sides of the Brampton Chain are stamped **"BRAMPTON."**

LARGE SALES and SMALL PROFIT with thousands of satisfied customers is our best advertisement. THE BRAMPTON CHAIN is made of self-hardening Steel; the strongest Chain in the World. All parts polished; fits sprockets (that are properly cut) without friction.

Some of the other chains may look like **THE CELEBRATED BRAMPTON CHAIN** because some of the other chain makers began to copy the design and shape of the **BRAMPTON CHAIN** links in 1904. They have improved somewhat on their copied design from time to time until these chains now look more like the **BRAMPTON CHAIN** than ever before. These chains somewhat resemble the **BRAMPTON** in appearance, but the manufacturers of such chains have been unable to copy the material —self-hardening steel.

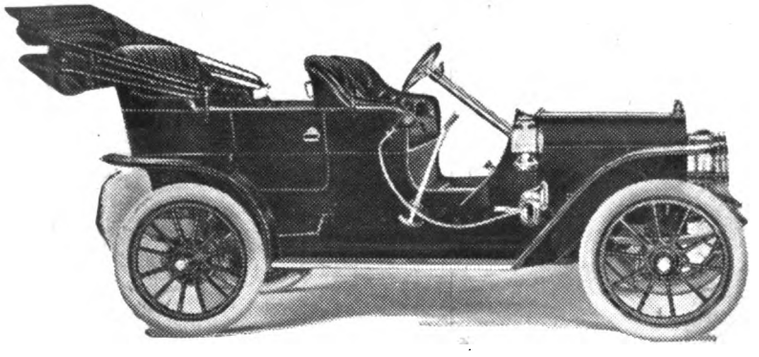
NO CHANGE IN THE BRAMPTON

There has been no change in the design, construction, material or finish of the **BRAMPTON MOTOR CHAIN** in the past ten years.—**"ENUF SED."**

PRICE

The price being equal, it's presumable you want the best, and full value for your money. In such cases, the **BRAMPTON FILLS THE BILL,** and the prices are the same to manufacturers, jobbers, dealers and consumers as any other chain of equal size. We have in stock chains to fit all American and foreign cars.

YOUR 1909 CAR



You can have the new car that you order fitted with the **CELEBRATED BRAMPTON CHAIN** if you order it that way. No extra cost to either you or the manufacturer. All standard sizes in stock to fit American and Foreign Cars at the same price as the other chains.

SPECIAL CHAINS TO FIT THE INDIAN MOTORCYCLE.

$2000

THE SELDEN CAR

Finished the Glidden Tour with a CLEAN SCORE and Was Deprived of a "Perfect Score" by a Technicality

We entered a stock car, which had already been run over 5,000 miles, without any shock absorbers, straps, bumpers or other safety appliances, complying strictly with the rules as to equipment. (All other cars were equipped with these devices.)

Our car was equipped with a speed indicator, the sprocket connection of which worked loose crossing the mountains in Western Pennsylvania and fouled our steering knuckle, making it impossible to avoid a large boulder in the middle of the road, and we broke a front spring in consequence.

The broken spring did not penalize us, nor the repairing of the spring, but because we used four machine-made nuts (instead of four hand-made nuts) we were disqualified from further contest for the Glidden Trophy.

Our car continued the tour as a non-contestant, checking in and out every day, observing all the rules and finished with a clean score.

It was in such good condition upon arriving at Saratoga that we made a non-stop run from Saratoga to Rochester, a distance of 272 miles on the following day without any adjustment whatever.

Our "extra parts" bag was not opened on the entire trip. No other car did any better.

COMPARE OUR CAR WITH OTHERS IN THE TOUR AND SEE WHAT WE HAVE ACCOMPLISHED

Demonstrating the highest quality of workmanship and material, durability, stability and the all-important fact that a strictly first-class gentlemen's car can be made and sold for $2000.

Why Pay Double the Price for a Name-Plate?

Duplicates of this car are now ready for delivery.

All our cars are sold with a guarantee and with all that we have out during the past season the cost of repairs amounts to little or nothing.

The "Silent Selden" (as the car has become known by its quiet running) is made on honor, a credit to the name of the man who invented gasolene automobiles, and every owner is proud of his purchase.

Superb riding, roomy tonneau, luxurious upholstery, smooth running, great hill climber, flexible and easily handled, economical in up-keep, stylish and attractive—the coming car of the multitude.

Now closing 1909 agencies—over half our output already spoken for. Good live agents wanted everywhere. Send for catalog and agency proposition.

BRUSH RUNABOUT WINS

THE SILVER CUP IN ITS CLASS AT THE

Fourth Annual Algonquin Hill Climb

OF THE CHICAGO MOTOR CLUB

against the Buick, Chalmers-Detroit, Moline and Jackson

MODEL B BRUSH RUNABOUT

There is nothing strange about the Brush Runabout winning hill climbs, endurance runs and such contests. It is not a toy as some would lead you to believe. It is a simple design made well—not a complicated design made cheaply.

The best demonstration of all of the Brush Runabout performance is the big Efficiency Run of five cars, now closing. They have stood up without trouble, worry or annoyance on this run, over every conceivable sort of road—sand, mud, rocks, hills, as they happen—everywhere between Boston, Washington, Kansas City, Minneapolis and Detroit. Write for booklet soon to be issued giving the data on this run.

THE INCOMPARABLE

WHITE

THE CAR FOR SERVICE

"Just Open the Throttle and Steer"

The above phrase summarizes the directions for operating the White Steam Car. No other car even approaches the White in the simplicity of the operations of driving. In the White, all speeds from zero to maximum are obtained by throttle control. There is no clutch, no changing of gears and no "cranking." The working parts do not need to be readjusted with each change in the atmospheric conditions. There are no "hit-and-miss" electrical devices and all parts of the mechanism are positive in their action. The supply of water and the supply of fuel are automatically controlled so that the temperature and pressure of the steam remain constant, without in any way engaging or requiring the attention of the operator. The White is thus the favorite car with those who wish to drive and to take care of their own machines.

Rambler

Model 34

Price, $2,250

Other Models, $1,200 to $2,500

TRY IT ON THE HILLS

Test this car at half speed on a hill or sand road where power and every ounce of it is needed. Notice how steadily and powerfully it pulls when running slowly under load.

The capacity of the offset crank shaft for doing this extra work is most noticeable at low engine speeds. All that power which in other engines is lost through friction on the bearings and cylinder walls, is added to the driving force by the Rambler offset crank shaft. It reduces friction; eliminates hammer on bearings; gives more power.

The straight line drive delivers the power direct and with least frictional loss to the rear axle. Let us demonstra e these features and the silence and the comfort of this car.

Tell our nearest representative to call at your home and take you to your place of business some morning in a Rambler. Or write your name and address and "Model 34" on a postal and mail to us today.

THE MOTOR WORLD

Volume XVIII. New York, U. S. A., Thursday, August 20, 1908. No. 21

MERGER PLAN APPEARS TO HALT

Rumored Hitch in Proposed Maxwell-Briscoe and Buick Amalgamation—Official Confirmation or Denial Withheld.

According to reports, a serious hitch has developed in the proposed amalgamation of the Maxwell-Briscoe and Buick interests into the projected "International Motor Co." with a capitalization of $25,000,000 more or less; indeed, one report states that all negotiations in this direction have been abandoned.

Confirmation of the stories, however, is not possible. Benjamin Briscoe, the president of the Maxwell-Briscoe Motor Co., is at present in the West where he will remain for a couple of weeks, ostensibly seeing western agents, although the portion of his time that is being spent in Chicago is suggested as having a bearing on the proposed merger. He could not be reached, of course, and the treasurer of the company, Richard Irvin, whose law and banking offices at 25 Broad street, New York, hold most of the details and transactions in connection with the negotiations, when asked yesterday as to the truth of the report that the plans for the combine has been dropped, said that he was in such a position at present that he could affirm or deny nothing in relation to the situation.

Motor Car Planning to Leave Detroit.

Pressed for a decision like a maid with two ardent suitors, the Motor Car Co., of Detroit, Mich., is undecided whether to move to an Ohio town that wants it or to a Michigan location that is making heavy inducements. In either event, the removal of the company's works from Detroit will take place in the not distant future.

Franklin Settles Foreign Suit.

Litigation between the H. H. Franklin Mfg. Co. and Messrs. Vander Wielen & Schwiebbe, of Belgium, in the matter of cancellation of trade mark "Franklin" registered in that country to cover automobiles, etc., has been terminated successfully by judgment of the court and agreement on the part of Vander Wielen & Schwiebbe allowing the Franklin company's registration to stand so far as automobiles and automobile parts are concerned; Vander Wielen & Schwiebbe, however, retain the registration so far as it applies to bicycles, bicycle parts, etc.

Herreshoff to Build Automobiles.

Charles F. Herreshoff, the Bridgeport (Conn.) inventor, designer and builder of the Den, the speedy motor boat, has severed his connection with the American & British Co., of Bridgeport, and is about to remove to Detroit, where there already has been organized under the laws of Michigan the Herreshoff Automobile Co. Herreshoff has designed a light automobile motor which he anticipates will create something of a furore and which will be incorporated in a car which will be produced by his new company in Detroit.

Bendix After Logansport Capital.

The citizens of Logansport, Ind., are being asked to subscribe for $75,000 worth of 6 per cent. stock in the Bendix Automobile Co., of Chicago, in return for which favor the Bendix concern will build a factory "in their midst," guaranteed to employ 200 men. The Logansport Industrial Association is looking into the project.

Rock Creek in Receiver's Hands.

With liabilities exceeding $16,000 and assets estimated by the proprietors at $26,000, the Rock Creek Auto and Wagon Works, of Washington, D. C., has gone into the hands of a receiver. Attorney Charles F. Diggs has been appointed to act in this capacity.

Forge Concern to Make Runabouts.

The Sizer Forge Co., Buffalo, N. Y., is working on the plans of a high-powered runabout with a view of engaging in its manufacture. They are in the market for a number of the necessary components.

MAY SELL POPE-WAVERLY PLANT

Receivers Get Favorable Offer for the Indianapolis Property—Negotiations in Progress Through Broker.

It is not improbable that the receivers of the Pope Mfg. Co. shortly will dispose of the Pope-Waverly plant in Indianapolis. It is known that an offer, accompanied by a substantial cash deposit, has been made for the property and that the receivers will ask the courts to set a date for a hearing on the proposal. It is expected that this application will be made to-day.

While a report from the West states the amount offered for the plant is $300,000, the report lacks authentication. Nothing definite has leaked out regarding this item, nor is the identity of the prospective purchasers traceable. They are conducting negotiations through an Indianapolis broker.

Shortly after the Pope Motor Car Co. went into the hands of receivers a quiet effort was made to form a company to purchase the Waverly plant, the movement going as far as the printing of a prospectus of the "Waverly Motor Car Co." Nothing came of it, however, and the present negotiations are said to have no connection whatsoever with the earlier movement.

Kissel Shot by Angry Employe.

L. Kissel, of the Kissel Motor Car Co., of Hartford, Wis., was yesterday shot by John Gerbier, an enraged employe, at the company's store in Milwaukee. Two bullets entered his head and one shot penetrated his stomach. As Kissel is 70 years old, his recovery is doubtful.

Plow Makers May Build Buggies.

The Shunk Plow Co., Bucyrus, Ohio, has built two motor buggies and now is testing them on the road, with a view of engaging in the manufacture of such vehicles. A definite decision will be reached after the test is completed.

IN THE RETAIL WORLD.

Armin E. Mill has opened a repair shop at 114-116 Brady street, Allijan, Mich.

A petition in bankruptcy has been filed against the Charleston Motor Co., Charleston, S. C.

G. A. Boener is building a garage at Cedarburg, Wis. He will rent cars, do repair work and deal in automobile supplies.

Burkhard Brothers are opening a big garage on Main street, St. Joseph, Mich. A renting service will also be maintained.

The W. H. Ellis Motor Car Co., Newark, N. J., will occupy its new garage and salesroom on Washington street, about September 1st.

W. O. Reilly, who has been operating an automobile livery between Greenbush and Roseau, Minn., has arranged to extend his business to Crookston.

George Stephenson's garage, 1543 Clarkson street, Denver, Col., was burned on the 13th inst. Two automobiles valued at $4,000 were rendered useless.

The Winton branch at Minneapolis, Minn., soon will be housed permanently in its own new building on Eighth street, north, near Hennepin avenue.

The Buick-Losey Automobile Co., of Indianapolis, has removed its sales and repairing rooms from Massachusetts avenue to 130-132 East New York street.

J. J. Cleary, 815 South Kedzie avenue, Chicago, has started a well equipped garage. Renting and repairing will be done, in addition to the regular garage service.

Leo F. N. Baldwin has bought out B. F. Blackington's interest in the Central Automobile Exchange, Fountain street, Providence, R. I., and now is sole proprietor of the business.

A White Garage has been established in San Diego, Cal., and another shortly will be located in Santa Barbara in the same State. Both will be branches of the White Garage of Los Angeles.

J. B. Kleese's garage, near Wick avenue and Wood street, Youngstown, Ohio, was burned Thursday, 30th ult. The bicycle repair shop of H. E. Woodworth, adjoining it, was badly damaged.

Robert Veitum and R. B. Wray, of Eugene, Ore., have formed a partnership to conduct an automobile business. Wray already has an agency, and the new firm plans establishing a well equipped garage.

The Diamond Rubber Co. will transfer its Boston branch to new quarters in the Pope building, 223 Columbus avenue, on September 1st. The branch has outgrown its present quarters at 174 Columbus avenue.

The Buick Motor Co., of Flint, Mich., has acquired the Buick-Waller Automobile Co., of Grand Rapids, for the purpose of establishing a western Michigan branch there. George W. Waller will be the manager.

Chester C. Henry opened this week in Newark, N. J., a new establishment where he will handle second hand cars during the summer, taking on a full line of a standard make of car next fall. His location is 283-285 Halsey street.

By a fire at Polk and Golden Gate avenue, San Francisco, on Monday, 3d inst., the Standard Motor Car Co., 503-5 Golden Gate avenue, lost its establishment. Three automobiles were the only propety saved. The loss is placed at $10,000.

The Utica Motor Car Co., of Utica, N. Y., has purchased the business of the Genesee Automobile Co., of Syracuse, N. Y., and will henceforth conduct establishments in both cities. The Genesee garage in Syracuse is at 242 West Genesee street.

H. C. Taylor, formerly of San Francisco, and J. H. Madison, of Petaluma, Cal., have formed a partnership and are fitting up a garage in the Hess block on Main street, Petaluma. They will handle automobiles, automobile supplies and sporting goods.

The garage and office of the White company at 220 Sixth street, S., Minneapolis, has been remodeled and redecorated. The front of the building, which formerly was occupied by the American Automobile Co., has been newly finished in white enamel.

Work was begun July 17th on the new garage at 233 Halsey street, Newark, N. J., to be occupied by the Atlantic Motor Car Co. The building will be three stories high, with a frontage of 50 feet on Halsey street, and will be constructed of fireproof brick.

A new tire house has been started in Wheeling, W. Va., to do a general agency and repair business. It is the Griffin Auto Tire Repair Works, located at Fourteenth and Chapline streets. Full equipment for extensive repair work has been installed.

Fred Weinmann has opened a garage at 1649 Vincennes avenue, Chicago Heights, Ill. He has an agency for the Cartercar and deals in motorcycles, bicycles, tires and general supplies. The garage is equipped with facilities for charging, vulcanizing and repairing.

The Boston store of the Dow Tire Co., has been removed to larger quarters. A commodious store at 889 Boylston street, in the newer automobile district, has been taken and a full stock of the Dow non-deflation tubes will be carried both for wholesale and retail purposes.

Paul Mulvane, Topeka, Kan., has sold his garage and automobile repair business at Seventh and Quincy streets, to Terry Stafford, formerly superintendent at the Smith automobile factory. He retains the tire and supply department of his business and will continue at the same location.

C. M. Coats is planning for the erection of a new garage on South Lasalle street, Aurora, Ill. The building will be constructed of cement and will be 160x60 feet in ground dimensions. The equipment will be thoroughly up to date, and a machine shop will form part of the establishment. Coats is located at present on South Water street.

The Thomas Flyer Renting Agency is a new branch of enterprise which Harry S. Houpt has added to his business at Broadway and Sixty-third street, New York City. Cars with either touring or limousine bodies are rented out, with drivers in correct livery, and the parties hiring them can put on all the front of private owners. Special rates are made for day trips.

Thomas B. Jeffery & Co., makers of the Rambler automobile, in the name of the Rambler Garage Co. of Chicago, will erect at 1218 Sheridan road, a 45-foot addition to the present spacious garage which has a 100-foot frontage. The addition will be three stories high, and will cost approximately $20,000. When completed it is claimed that the garage will be the largest public structure of the sort in this country.

The Chelsea Auto Storage Co., of 520 West Thirty-seventh street, New York City, is in proceedings for the dissolution of the corporation, and Judge Erlanger of the Supreme Court has appointed Arthur D. Truax as receiver. The action is brought by Directors Arthur M. Von, Lester F. Albro, and Clement L. Stephenson. The business was started several years ago by Von and Albro, and was incorporated April 10, 1907, with a capital stock of $75,000. The present assets are $1,150.

Pope Receivers Report for July.

According to the report of the receivers of the Pope Mfg. Co. in Connecticut, for the month of July, with the clerk of the Superior Court at Hartford, the cash balance in the banks and at the office at the end of the month was $326,363.29, while at the first of the month it was $587,338.47. This lessening of the cash was largely due to a transfer of $300,000 to the receivers in New Jersey for the payment of a second creditors' dividend. The receipts for the month were $121,658.30, of which the chief item was $99,227.16 in sales. The disbursements for the month were $382,633.48, of which $300,000 went to the receivers in New Jersey, as stated, while $76,871.83 was spent in materials and supplies, pay rolls, selling expenses, taxe and royalties. The last item amounted to $11,742. In addition, liabilities for materials, pay rolls, etc., accrued to the amount of $23,031, together with an interchange of liabilities and credits with the receivers in the other districts.

Castle Did Not Make the Motion.

It transpires that Fred Castle was not the member of the Motor and Accessory Manufacturers who, at Atlantic City, introduced the resolution committing the organization against participation in the next Chicago show unless the price of space is reduced. The report to that effect did Mr. Castle an injustice and apparently grew out of the fact that it was he who made known that the executive committee had taken action of the sort.

THE WEEK'S INCORPORATIONS.

Chicago, Ill.—Berliet Import Co., under Illinois laws, with $2,500 capital; to deal in automobiles and machinery and parts therefor.

Denver, Colo.—Auto General Supply Co., The, under Colorado laws, with $18,000 capital. Corporators—J. C. McGill, George H. Phelps.

Chicago, Ill.—Perfection Emergency Tire Co., under Illinois laws, with $25,000 capital. Corporators—G. C. Grable, W. R. Hartley, D. W. Norris.

Dover, Del.—Co-operative Garage Co., under Delaware laws, with $150,000 capital. Corporators—J. W. Ebbs, F. H. Lord, H. H. Nieman, New York City, N. Y.

Cleveland, O.—Cleveland Auto Cab Co., under Ohio laws, with $150,000 capital. Corporators—A. C. Miller, J. C. Brooks, A. T. Welch, M. C. Mulhall, George A. Howells.

Boston, Mass.—Taxi Service Co., under Massachusetts laws, with $120,000 capital; transportation business. Corporators— J. L Miller, Boston; C. F. Lovejoy, Lynn, Mass.

Richmond, Va.—Foster Motor Car Co., under Virginia laws, with $3,000 to $10,000 capital. Corporators— C. L. Young, Norfolk, Va.; L. M. Foster, Nixon Ball, Richmond, Va.

Chicago, Ill.—Cross Tread Anti-Skid Co., under Illinois laws, with $5,000 capital; to manufacture automobile accessories. Corporators—J. J. Sheridan, C. R. Murphy, C. G. Hutchinson.

Milwaukee, Wis.—W. L. Hibbard Motor Car Co., The, under Wisconsin laws, with $50,000 capital; garage business. Corporators—William L. Hibbard, William T. Bradley, James A. Wright.

Jersey City, N. J.—McKeen Motor Car Co., under New Jersey laws, with $1,000,000 capital; to manufacture motor cars and engines. Corporators—G. E. Downes, B. F. Russell, T. F. Barrett.

Cortland, O.—Cortland Transfer Co., The, under Ohio laws, with $10,000 capital; to operate automobile line. Corporators—Lewis Hutton, E. E. Faunce, J. H. Faunce, F. M. Griffin, H. S. Post.

Chicago, Ill.—Crescent Motor Car Co., under Illinois laws, with $100,000 capital; to manufacture and deal in motor cars and auxiliary machinery. Corporators—F. D. Moor, C. P. Hatter, W. J. Crumpton.

Chicago, Ill.—Standard Automobile Supply Co., under Illinois laws, with $10,000 capital; to manufacture and deal in automobiles, etc. Corporators—W. F. McCarthy, George B. Levy, A. S. Henley.

New York City, N. Y.—Goodman Sales Co., under New York laws, with $500 capital; automobiles. Corporators—Edwin D. Hayes, Martin C. Ansorge, Joseph Thomas, 115 Broadway, New York City, N. Y.

New York City, N. Y.—Detroit Cadillac Motor Car Co., under New York laws, with $5,000 capital. Corporators—William H. Murphy and Wilfred Leland, Detroit, Mich.; Henry B. Potter, New York City, N. Y.

Buffalo, N. Y.—Brunn's Carriage Mfg. Co., under New York laws, with $100,000 capital; to manufacture wagons, carriages, automobiles, etc. Corporators—H. Brunn, E. W. Harrington, F. A. James, Buffalo, N. Y.

Los Angeles, Cal.—Western Multi-Motor Co., under California laws, with $200,000 capital. Corporators—John Braunwalder, Robert B. Macintosh, Irving B. Stillan, Helen M. Braunwalder, Elise M. Macintosh.

Grand Rapids, Mich.—Muller Auto Mfg. Co., under Michigan laws, with $2,000 capital. Corporators—Joseph Renihan, William A. Bates, William F. Stadel, Charles E. Hessey, A. J. Miller, Harry W. Bissell, Michael Colleton.

Buffalo, N. Y.—Chief Motor Co., under New York laws, with $250,000 capital. Corporators—Earl W. Bailey, 27 Putnam street; G. Willis Wheeler, 80 Ashland avenue; Porteus R. Cunningham, 168 Richmond avenue, Buffalo, N. Y.

New York City, N. Y.—George H. Tyrrell Co., The, under New York laws, with $5,000 capital; garage. Corporators—George H. Tyrrell, Joseph F. Althause, 2639 Webster ave.; William F. Burrough, 280 Broadway, New York City, N. Y.

Hasbrouck Heights, N. J.—Enterprise Automobile Co., under New Jersey laws, with $100,000 capital; to manufacture automobiles, engines, etc. Corporators—J. F. Coleman, J. L. Lotsch, E. S. H. B. Schultz, Hasbrouck Heights, N. J.

New York City, N. Y.—Co-operative Garage Co., under New York laws, with $10,000 capital. Corporators—J. Reibstein, 76 William street, E. W. Webb., 15 William street, New York City, N. Y.; F. L. Tyson, 44 Court street, Brooklyn.

New York City, N. Y.—Broc Auto Ignition and Supply Co., under New York laws, with $5,000 capital. Corporators—Paul L. Snutzel, 116 Nassau street; James Parkes, 15 Wall street; Albert De Barres, 1692 Broadway, New York City, N. Y.

New York City, N. Y.—Suburban Auto Express Co., under New York laws, with $25,000 capital; transfer and express business. Corporators—A. N. Bingham, New Rochelle, N. Y.; R. G. Hamilton, New York City, N. Y.; M. M. Whipple, Brooklyn, N. Y.

New York City, N. Y.—Moon Motor Car Co. of New York, under New York laws, with $5,000 capital. Corporators—Charles A. Duerr, 325 West Ninety-third street; Edward W. Elverson, 2186 Broadway; Harry Eckhard, 111 Broadway, New York City, N. Y.

New York City, N. Y.—Knickerbocker Tire and Repair Co., under New York laws, with $10,000 capital. Corporators—William J. Staunton, 321 Pacific avenue, Jersey City, N. J.; John J. Walsh, 229 West 148th street, Charles P. Bispham, 601 West 169th street, New York City, N. Y.

Ogden, Utah—Ogden Canyon Automobile Co., under Utah laws, with $25,000 capital; to operate line of sight seeing cars. Corporators—J. S. Corlow, Albert Scowcroft, Joseph Decker, D. A. Smyth, M. S. Browning.

Wilmington, Del.—Auto Co. of Wilmington, The, under Delaware laws, with $10,000 capital; to deal in automobiles and automobile supplies, gas engines, etc. Corporators—A. B. Wilding, George B. Elliott, C. E. Taylor, W. D. MacMillan and Morris Bretzfelderall, Wilmington, Del.

New York City, N. Y.—Willis Cab and Auto Co., under New York laws, with $85,000 capital; to deal in horses, to manufacture and deal in carriages, automobiles, etc., livery and boarding stable business. Corporators—J. S. Walton, A. J. Wolff, A. B. Stopel, New York City, N. Y.

Bristol Engineering Co. Incorporates.

The Bristol Engineering Co., which already has begun making "blue cabs" for the American Taxameter Cab Co., has filed a certificate of incorporation under the laws of Connecticut. This disclosed that the concern is capitalized at $500,000. The manufacture of taximeter cabs and automobiles is specified as its object. The incorporators are Albert F. Rockwell, president of the New Departure Mfg. Co.; De Witt Page and Charles Treadway, all of Bristol, Conn.

To Make Motor Buggies in Jacksonville.

Stumps and rocks, mud and ditches, make a special type of automobile more or less necessary for use in Florida, and to meet the demand for a style of vehicle that is suitable, the Southern Automobile Mfg. Co. has started operations in Jacksonville. The product will be a motor buggy with an especially high clearance, a 12 horsepower air-cooled model to sell for $500, and a 20 horsepower, water-cooled model for $650.

Grand Haven Has Vision of a Factory.

Having "solved the gasolene engine problem," Charles Boyden, of Grand Haven, Mich., is dangling the possibilities of an automobile factory before the citizens of Holland, a town in the same state. Capitalists in the latter place have been interested to a point where a meeting is to be held to pass on the proposition of backing the proposed plant.

Pontiac Concern to Assemble Cars.

Heavily laden with name, the Schuler-Morris-Jones Motor Car and Electric Co. has started up in Pontiac, Mich, to manufacture a line of cars from standard parts. It will also do rebuilding and repair work.

Brush Catches on in South America.

Brush runabouts are "catching on" in South America. The Brush Runabout Co. have just closed with Pratt & Co., of Buenos Aires, for their sale in Argentina.

FRANKLIN Automobiles

If talking built automobiles there would be a number of them like the Franklin this year.

There never was a heavy over-weighted Franklin automobile. There never was one without good big carrying ability and speed and power in proportion to its weight; never one that didn't wear phenomenally and cool perfectly, and do its work at the lowest operating cost. And there never was a hard-riding Franklin.

The Franklin has always been simple and compact and superbly high grade; roomy and luxurious without awkward bulkiness; and extremely facile to manage and control.

We have always contended that this is the only practical sensible kind of an automobile for American roads and city streets. We have refined and developed the Franklin consistently along this same line from the start, seven years ago.

Other manufacturers laughed at our ideas then. To-day, the more wide-awake ones are trying to copy them.

But the Franklin qualities are built into the automobile. They are founded in the Franklin design. You cannot produce the combination of efficient high power with strength, light weight and easy-riding quality except through the Franklin air-cooled engine, the Franklin laminated wood frame and the Franklin full-elliptic spring suspension.

You cannot talk these qualities into existence. You cannot produce them at their best in a day or a year.

According to the old proverb—"A stern chase is ever a long one."

Weigh any Franklin; ride in it; look into its operating cost and its endurance; look at the Franklin record in the great economy test, the famous run across America, the Chicago to New York run, and the latest Glidden Tour. Then judge for yourself how near any other automobile has yet come to the Franklin standard.

16 H. P. 4-cylinder Runabout	$1,750	16 H. P. 4-cyl. Touring-car	$1,850
28 H. P. 4-cyl. Touring-car or Runabout.	2,850	42 H. P. 6-cyl. Touring-car or Runabout.	4,000

Cable Address, "MOTORWORLD," NEW YORK.

Entered as second-class matter at the New York Post Office, November, 1900.

NEW YORK, AUGUST 20, 1908.

Credit Where Credit is Due.

Farcical as was the plan for the so-called New York to Paris "race" in its original conception, including as it did a route through portions of Alaska and Northern Siberia, where the dragging of the cars on dog sledges as freight obviously would have been necessary, the later modifications of the itinerary served to bring it more within the bounds of common sense, and the actual performance of the winning Thomas car was such as in itself to redeem the whole affair from the absurdity which threatened it.

No matter how loose and ill-considered the ideas of the promoters of the contest may have been as to its conduct, the steady and faithful work of the one American competitor in plugging ahead on its own power for 12,116 miles, following the prescribed course and in ultimately getting to the point it set out for, without resort to railroad trains or similar aids on land, is justly calculated to arouse not only admiration but enthusiasm. If the promoters did nothing more than set in motion so striking an exhibition of grit and endurance on the part of the successful drivers and the demonstration of more or less typical advantages and points of superiority in American automobile design and construction for hard tourinug service, they are entitled to a certain measure of credit.

Effect of Hats on Limousines.

Fashion as a governing factor in automobile design, and more particularly in respect to the construction of bodies, has long been recognized as of marked weight. Further, that the fair sex exercises a strong influence on the sales of certain models and so has come to be directly catered to by the body designer also is known. But that changes in the mode of feminine garb could in any way be expected to control the layout of automobile bodies never would be suspected. Nevertheless such is the case. In proof of which it is announced that the heights of forthcoming limousine bodies from floor to ceiling will be somewhere about two inches lower. The only reason to which this change is ascribed is found in the forecasted lowering of fashionable headgear during the coming winter.

A striking instance of the way in which the automobile designer is forced to attend to the most trivial and apparently irrelevant matters, is furnished by the case in point. Before deciding upon the heights of his limousine designs, for example, one New England body maker, who numbers among his patrons several of the best known makers in the country, was at some pains to communicate with representative milliners in New York City in order to obtain authority for the change. For it must be understood that inconsequential as it may appear, this very item might prove the deciding factor in the choice of a car which was to be used almost wholly for evening and afternoon duty about town. With the absolute assurance that hats are coming down this fall, the designs in contemplation were carried forward with absolute confidence of their ready acceptance at the hands of the public.

Another, though less striking example of the same principle is found in the case of a car manufacturer in the Middle West who makes it a point to carry in stock a complete line of top, upholstery and floor covering materials in various colors and to keep a certain fixed number of stock bodies on hand at all times worked up to the color coat, but not finished. By this means customers are enabled to make an absolute selection of finishing materials and colors and to secure what is virtually a "special finish" order in but little more time than would be required for a stock delivery from the factory. The object of this is plainly that of catering to the wishes of the buyers' wives quite as much as to any strong inclination on the part of the buyers themselves to adopt any but the standard finish chosen by the maker for the bulk of his output. It is not difficult to pick out other instances of a less conspicuous nature in which the effort is made to exert a direct appeal upon the ladies. That such appeals have equally direct and evident effect upon the market is beyond question, though the fact is not generally appreciated.

The Matter of Sanctions.

Why the Lowell Automobile Club or any other organization or any person should be bluffed into seeking a guarantee or promise from the misnamed Automobile Club of America that it will not disqualify entrants in events, such as the Lowell road race, that are sanctioned by the American Automobile Association, is at once comprehensible and incomprehensible.

If such clubs or persons understood that a large part of the anti-A. A. A. stuff that appears in the New York newspapers, and which is copied by other prints, is the work of paid press agents and men with grievances, and that much of the remainder is "colored" by aggrieved reporters to whom the Automobile Club of America, of New York, has presented what are practically free cards of membership, such clubs or persons very readily would discover the quality of the milk in the A. C. A. cocoanut.

When the Automobile Club of America this week announced that any man or car, or maker or agent of such car, who competes in an "international race" not sanctioned by itself, men and car alike will be disqualified from competing in such races both here and abroad, it could go no further. As the accredited Guardian of Europe's Interests in America the step is perfectly logical. Its officials well know what every unbiased man knows, i. e., that the extent of its dominion begins and ends there. As the Vanderbilt cup race is the only recognized "international race" run in this country, this dominion is extensively

Digitized by Google

circumscribed. Every unbiased man knows as well that the body which controls and administers the sport in this country is the American Automobile Association, and it is the only organization with which any sports promoter need deal. It will be a sorry day for real Americans—importers and "soreheads" excepted—when the Recognized Automobile Clubs of Europe, through the Automobile Club of America, or any other club, for that matter, can control or dominate the sport on these shores.

Anyone who applies to the A. C. A. for a "sanction" or who fears its "disqualification" either is ignorant of the situation or is easily bluffed. The A. C. A. is first and last a purely local club, even if Europe is so blind that it cannot discern this glaring truth.

The Motor World holds no brief for the American Automobile Association. On occasion, it has not spared criticism, but it is the recognized American national institution, and is of, for and by Americans. Its sanctions are the only sanctions required in America, and the penalty for failure to obtain them is clearly defined by its rules. It is the hope of the Motor World that in bringing these rules to bear, the association will not temporize, but will apply them promptly and with vigor and thoroughness.

Influence of Prices of Replacements.

Interchangeable production when carried out on a large scale brings with it other advantages besides that of reducing the first cost of the finished product. Among them one which has not as yet received its due of public notice is that of the reduced cost of replacements. Formerly, whatever exorbitant charges may have been levied upon the buyer of a car, his continuous use of it was rewarded almost without exception by charges on the inevitable replacements which amounted in many cases to what he not inaptly termed robbery. The immediate result was to swell the cost of car maintenance to a totally disproportionate figure and to help to sustain the expensive reputation of the machine. That a number of makers have been able, by virtue of improved methods of manufacture to eliminate these exaggerated costs is a strong point in their favor.

A telling instance of the way in which this movement may affect the local markets recently developed in a study of garage conditions in the West. It was found that in one city car owners and repairmen, whenever possible, were purchasing certain replacements from the stock of a particular agent regardless of the make of car involved. The secret of the large parts business done by this dealer turned out to be the extremely low price asked by the maker whom he represented for all extras and replacements on his own machines.

These prices were so in contrast to those asked by other makers that in one case the remark was made: "After having my eyes opened, I am certain that were I about to buy another car, I should be influenced very largely by the economy of upkeep which this maker brings about by the reasonable prices asked for his extra parts."

The advantage to the maker who is in a position to supply replacements at very low figures needs no comment. The ability to quote advantageous prices on such parts is an index of close methods of interchangeable production which in itself is a good advertisement of careful construction of the finished car. The successful marketing of such a product should constitute a useful weapon of publicity and it is surprising that those makers who are in a position to do so have not made more capital of it.

As the cauldron of national politics begins to bubble, preparatory to its imminent seething, the gravest anxiety rests on the respective campaign managers as to which banner the Professional Chauffeurs Club of America will choose as a standard under which to carry out its resolution to "take an active and energetic part in the coming campaign for the election of a president of the United States." Inasmuch as the club has decided that "there hardly is any other collection of individuals that can do more to bring about the election of a president" the political situation is peculiarly intense until the presidential candidates and the public can learn which way the cat is going to jump, and whether the club members will lean to Labor, of which they are part, or to Capital, on whose prosperity they are exceptionally dependent. That candidate who first espouses the club's "platform" for the abolition of speed traps and the removal of justices of the peace whose minds are on the bias, will have the first call on the privilege of moving his household effects into the White House, despite the constitutional prohibitions on his meddling with the purely state and municipal matters that the chauffeur president-selectors so gravely offer as national issues.

COMING EVENTS

Sept. 1, 2, 3, and 4, Chicago, Ill.—Chicago Motor Club's postponed 1,000-mile reliability run.

September 5-9, Los Angeles, Cal.—Automobile Dealers Association's reliability run to San Francisco.

Sept. 7, Columbus, Ohio.—Columbus Automobile Club's race meet.

September 7, Lowell, Mass.—Lowell Automobile Club's 200 miles road race, on Merrimac Valley boulevard.

September 7, Columbus, Ohio.—Columbus Automobile Club's race meet.

September 7-12, Hartford, Conn.—Connecticut State Fair Association's outdoor show and grand circuit races at Charter Oak Park.

September 11, Springfield, Mass.—Springfield Automobile Club's hill climb on Wilbraham hill.

September 12, Louisville, Ky.—Louisville Automobile Club's race meet at Churchill Downs.

September 14, Chicago, Ill.—Chicago Motor Club's annual economy run.

September 20, San Francisco, Cal.—Olympic Athletic Club's race meet at Tanforan Park.

September 23-24, Boston, Mass.—Bay State Automobile Association's 24 hours endurance run, Boston to Bretton Woods, N. H.

October 6-9, Chicago, Ill.—Chicago Motor Club's 1,000 miles reliability run.

October 7, Philadelphia, Pa.—Quaker City Motor Club's 200 miles road race, Fairmount Park.

October 10, Long Island—Elimination trials for Vanderbilt cup contest.

October 24, Long Island.—Vanderbilt cup contest.

November 26, Savannah, Ga.—Automobile Club of America's (New York), 400 miles outlaw race for foreign cars.

December 31-January 7, New York City—American Motor Car Manufacturers' Association's annual show in Grand Central Palace.

January 16-23, New York City—Association of Licensed Automobile Manufacturers' annual show in Madison Square Garden.

January 23-30, Philadelphia, Pa.—Philadelphia Automobile Trade Association's annual show.

February 6-13, Chicago, Ill.—National Association of Automobile Manufacturers' show, Coliseum.

February 27-March 6, Hartford, Conn.—Automobile Dealers Association's annual show.

CLIMBING THE ALGONQUIN HUMPS

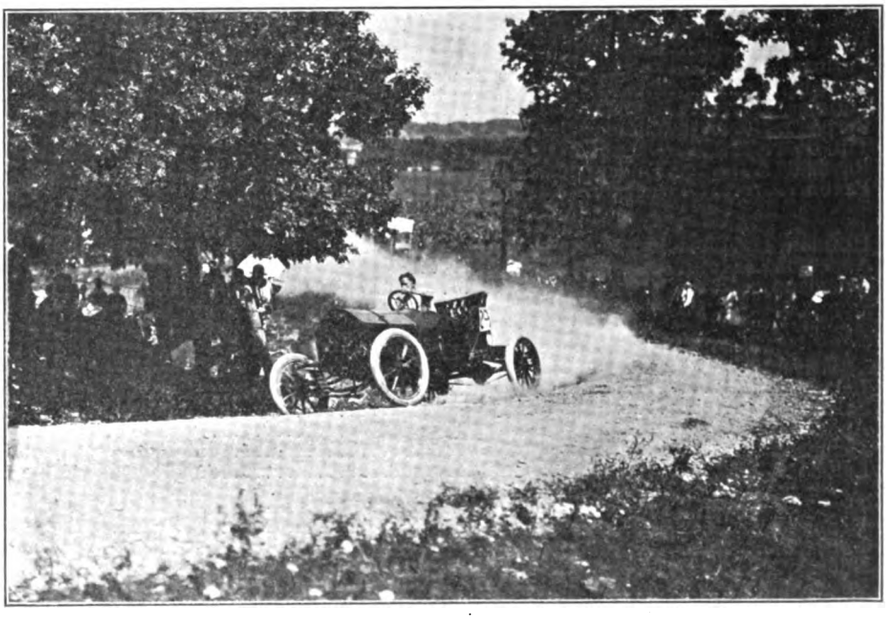
Good Contests in Chicago's Postponed Meet —Winners by the Watch and Winners by Mathematics.

Scratch the civic pride of a Chicagoan and he will proudly declare that Chicago never does anything by halves—not even in respect to automobile hill climbing contests. While other cities have been content that one hill should suffice for a contest, Chicago, that is, the Chicago Motor Club, last year set the fashion of using two different grades to decide results, which were arrived at by intermixing sport and mathematics.

VIEW OF A SINUOUS ROAD ON PERRY HILL

No other organization saw fit to follow the fashion, but the fact did not discourage the Chicago club, and it again tried the double dose on Friday last, 19th inst., rain having caused a postponement from June last. As Chicago itself is as mountainous as a ball room floor it was necessary to journey to the little town of Algonquin, Ill., in order to find something resembling a hill. There are two of them there, both short and fairly steep—Perry's hill and Phillips's hill, as they are locally known.

The contest was an all-day affair. The morning "matinee" occurred on Perry's and the afternoon performance on Phillips', and the shades of night were falling fast before anyone knew who was who or what was what. For being run on the mathematical plan, it was not until the wise men with nimble pencils had multiplied, subtracted and divided and otherwise indulged in mental gymnastics that the winners had evolved. This sort of contest carries pleasure even to the many losers. The victory is not always to the swift, and as a result, though the swift may not figure at the top of the mathematicians' tables, they nevertheless may shout from the house tops and in the advertising columns: "We didn't win, but we made the fastest time on Phillips' hill'—or on Perry's hill, as the case may be, all of which is so very enlightening to the great green public that it well may be pardoned for scratching its head.



The time of each ascent on each hill was recorded separately, and from these marks the winners were determined in accordance with a formula adopted by the club, which called for a multiplication of the average A. M. and P. M. time, by the piston area, and a division of this result by the weight of the car and driver. Fast time was made in the various classes, although, according to the formula, first place did not necessarily go to the fastest car in every instance. Following the first five events, there were two free-for-alls, the winners of the latter being determined by time alone.

Records for the hills commenced to go, when in the first event, which was for motor buggies, De Launty beat the record of last year by 23 seconds, with his Bendix, although when the percentage was calculated, first place went to Renegar driving a Holzman. In Class B, for light cars with a piston area less than 50 square inches, Lobdell scored decisively at the wheel of a Brush runabout.

Drivers McLean and Miller made good in the next two events, the former in an Apperson making the best percentage of the day in any of the events under the formula. In the class calling for an area of more than 90 square inches, Hoffman was an easy winner in his Pierce mount. In this event, George Salzman, at the wheel of the Thomas "Six," made a showing on Perry's hill when he sent her up the quarter mile 8 per cent. grade in 25⅗ seconds.

Frank Leland was the star of the day when he shot his Stearns "Six" over Phillips' hill in the first free-for-all event at a clip less than a mile a minute. He splintered the record of 33⅕ seconds for the half-mile grade, when he covered it in 0:29⅗, and won the special silver trophy offered by the citizens of Algonquin. In this ascent, Salzman tied with him on the Perry slope, covering it in 24⅗ seconds.

In the second free-for-all, Al Dennison cleaned things up with a Knox, his fast time for the two hills being 0:24⅕ and 0:31. A. W. Greiner, an amateur, made good time in the morning, although he had no one to compete with him in his class.

his mount during the early trials on Perry's hill and when the car reached the summit at high speed, it left the road and slewed into an official tent, barely missing several of the judges. Later in the day, the same driver let his car get away from him while rounding a dangerous curve. The machine charged the large crowd, when it plunged into the roadside, injuring three persons.

Charles W. Van Sickle, while riding a 7 horsepower Indian motorcycle up the incline at a speed of 65 miles an hour, struck a stone and was thrown about 25 feet. Luckily, he picked out a soft spot and landed unhurt. The summaries are given in the accompanying table.

Mechanical Efficiency Test Scheduled.

On September 16 and 17, there will be held a mechanical efficiency test on Long Island, under the auspices of the New York Automobile Trade Association. Arrangements have been made with this body and plans formulated, the actual direction of affairs being in the hands of W. J. Morgan. The contest will start early in the morning from New York and run to Montauk Point, with a halt for luncheon at Blue Point. From Montauk, the night stop, the contestants will, in the morning, return to New York by a different route.

The idea is to hold a price class run, for stock cars, dividing them according to list prices and establishing checking controls along the line. Strict observation of cars' performances will be kept and no repairs, aside from ordinary adjustments will be permitted. There will be two distinct general classes: one for manufacturers and dealers, and the other for amateur owners, driving their cars. There will be eight divisions as regards prices, ranging from $850 to $4,000. A special taxicab division may also be added. Prizes will be awarded to first, second and third places in each class.

Tourists in Turkey are permitted by the customs officials to take six months to pass through the country. On entry, a sum varying from $110 to $176 is levied on a machine. This amount, less 1 per cent. "transit duty," is returned if the car leaves the country within the six months.

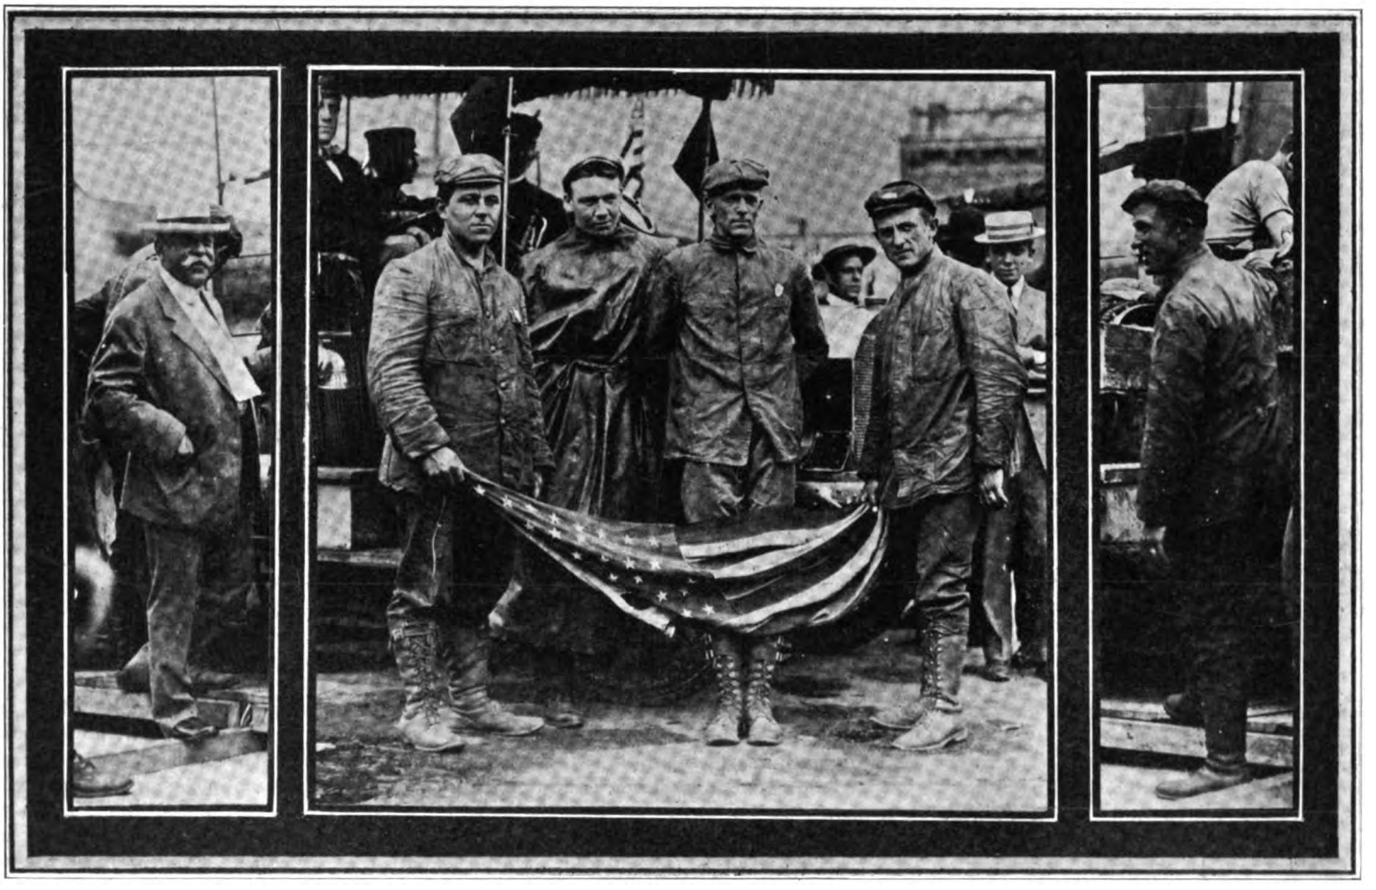
WELCOME TO GLOBE CIRCLING CAR

Gotham Hails Victorious American Entry in New York-Paris Contest—Schuster Tells Story of the Struggle.

It certainly was a glorious reception that was tendered to the three Georges of the New York-Paris Thomas car crew when they arrived home on Saturday, August 15. George Schuster, who drove the victorious car from San Francisco, his mechanician, George Miller and "War Correspondent" George McAdam, were mighty glad to get back to America again and shake hands with E. R. Thomas, Harry S. Houpt, J. E. Bowles, et al.

As soon as the conquering heroes descended the gang plank of the steamer La Lorraine, a string of Thomas cars and one Zust machine, escorted them to the new custom house, where after some delay, the red tape incidental to the clearing of the winning car was accomplished, although the machine itself could not be unloaded from the steamer until the following Monday. From the Custom House, the caravan proceeded to the Stock Exchange. The drivers were introduced to a number of the foremost financiers in the office of A. O. Brown, and from there the party drove through Wall street and up Broadway amid a constant cheering, to the Automobile Club of America, where a luncheon was served.



Here Robert Lee Morrell made the formal address of welcome. He praised Mr. Thomas for his sportsmanlike attitude in entering the only American car in the New York-Paris event, and also in the Grand Prix in France. Mr. Thomas replied that while at first he did not take the matter seriously, when the time came, he could not bear to see four foreign flags in a race starting across the United States without the Stars and Stripes. He frankly believed at that time that none of the cars would ever complete the trip. He had been told that it would be impossible for the contestants to cross the State of Wyoming, let alone Siberia, and he was willing to believe it; nevertheless he was confident that an American made car could "size up" with foreigners and go as far as the rest. Later Mr. Thomas, who was extremely modest in mentioning the name of his car, announced that it would be driven back to Buffalo and after a little overhauling would be entered in the 24 hours race at Brighton Beach on September 18th.

Schuster, when called upon, showed that he was more of a driver than an orator, which he admitted; nevertheless he made an interesting little speech, praising Mr. Thomas, Montague Roberts, who drove the car from New York to Cheyenne, and the other drivers, Matthewson, Brinker and Miller, who had helped carry the car to victory. He said it would be a great gratification to him to pilot the car into Buffalo, his native city.

Harry Houpt, the Thomas agent in New York, gave all the credit for entering the car and getting Mr. Thomas interested in the venture, to John E. Bowles, of the Houpt company, who wanted to enter a Thomas car in the race from the very outset.

After George Miller, the smiling mechanician of the crew, had paid a great tribute to his fellow-sufferers in the race and a few more prominent automobilists had said a few words, it was announced that Jefferson De Mont Thompson was ready to award Schuster the $1,000 cash for carrying the American flag around the world. Plans for a banquet this (Thursday) evening, at the Automobile Club of America and a trip to Oyster Bay to introduce the drivers to President Roosevelt next Saturday, were also announced.

But on Monday afternoon, this week, the car itself came into its glory. Preceded by

a band playing patriotic airs in a sight-seeing automobile, the doughty battered car, with the flag that it had carried around the globe, led the procession of 50 decorated cars to the City Hall. Schuster was at the wheel, Montague Roberts, Miller and McAdams, being the other occupants, while the following machines carried some of the foremost men in motordom.

The parade made a stop in City Hall Park and the Thomas crew were taken into Acting Mayor McGowan's office and introduced. After making a short speech to the crew, the acting mayor came out and seated himself at the wheel of the victorious car, smiling blandly and praising the wonderful American achievement, the cameras clicking meanwhile.

The procession then streamed up Broadway to the Houpt headquarters, the band banging out inspiring music and the mud-covered winner making more music with its noisy cylinders firing just as efficiently as the day it left Times Square, six months ago.

WELCOMING CROWD AT THE PIER

PREPARING FOR TRIUMPHAL PARADE

On February 12, when this race began, there were six starters, including the American, one German, one Italian and three French cars. One French car, Siziare et Naudin, retired after running a hundred miles on the road; the second French car, the Moto Bloc, ran 1,300 miles to Clinton, Iowa, and then gave up the contest; the third French car, the De Dion, made the trip across the United States to San Francisco, shipped to Seattle, and thence to Japan, thence across Japan, but retired at Vladivostok, while the German Protos car, through a "misunderstanding," was shipped by freight from Idaho to Seattle, being then 1,100 miles and 23 days in time behind the American car.

After the withdrawal of the De Dion car the American, Italian and German cars were left to cross Asia. The Thomas took the lead at the start, but at Pogranitchnaya stripped a driving gear and was delayed five days in repairing the damage. The Protos meantime continued, and, although the Thomas crew made valiant efforts to overtake the Germans, the Protos led into Chita by two days and won the $1,000 cup offered by the Trans-Siberian Railroad for the car arriving first at Chita. The Americans continued in pursuit of the Germans and overtook them on the shores of Lake Baikal, but were unable to load on the boat which carried the Germans across the lake, and were compelled to wait 24 hours for the next boat. A lead was obtained through Irkutsk Kansk and through Krasnojrsk, but they were overtaken at Tomsk, 3,408 miles from Vladivostok. The Thomas led the way from then until it crossed the Russian border, where it again stripped a gear and was delayed five days, allowing the Germans once more to take the lead and show the way into Moscow and St. Petersburg, capturing the second $1,000 prize offered by the Russian Automobile Club. Over the splendid roads of Europe it was an easy matter for the Germans to maintain this advantage into Berlin and Paris. They were two days ahead of the Thomas in Berlin, finishing in Paris the day that the American car reached the Kaiser's capital. The Thomas, with 30 days allowance, took four days for the final run from Berlin to Paris, winning the race by 26 days.

The record of the cars is interesting; it shows the Thomas covered 3,936 miles in America in 42 days, and 8,280 miles in Asia and Europe in 70 days, a total of 12,116 miles in 112 days. The Protos covered 2,607 miles in America in 65 days, and 8,280 in Asia and Europe in 65 days, making a total of 10,887 in 130 days. These figures best illustrate the relative merits of the performance.

In speaking of the remarkable contest Schuster said:

"The trip was a most remarkable one from start to finish, but none of the three of us would undertake it again for any consideration," he said. "No one has any idea of the strain under which we labored as we sought to overtake the flying Protos or rushed on to maintain the lead which we had regained. When we stopped for rest our sleep was broken with nightmares of the other car overhauling and passing up or leaving us far behind and we were driven to keep on the road for practically 20 hours out of 24. This, continued for nine weeks, was a terrific strain, but we went through it successfully and can look back on it as an experience of a lifetime.

"When we left San Francisco the Protos was not yet at Ogden, Utah, where, the rough journey across the States having disabled it, it was shipped to Seattle. We had a comfortable lead on the De Dion and Zust, and on that account, after reaching Seattle, we went ahead to Valdez in order to see for ourselves what the conditions were in Alaska. It was decided to abandon the arctic portion of the journey, order coming that the cars should proceed via Vladivostok, through Asia and Europe to Paris.

"Japan was a picnic, with a few scares thrown in when the narrow, flimsy bamboo bridges had to be crossed, and some strenuous calls for the low gear on the mountain passages. Nevertheless, the kindly hospitality of the natives caused forgetfulness of all the difficulties, leaving only the memory of the good time spent in crossing the land of the little brown man.

"The trouble began when Vladivostok was left behind. The roads were not any worse than in America, but when at home we could always count on food and a clean hotel at the end of a journey. In Manchuria and Siberia there was neither, the hotels being bug-ridden hovels that made one glad to sleep on the veranda, in stables, in wagons, on the ground—anywhere, in fact, but under the roof of a house. Food was as bad, the staple article of diet apparently being a coarse black bread, the crust of which could be eaten, but the inside of which was absolutely indigestible. Eggs could be obtained sometimes, tea always, coffee never.

"Rain accompanied us when we left Vladivostok and remained with us for 18 days in succession. At that time we had not taken to the railroad track, but were endeavoring to push along over the soft, boggy country. On the first day we covered 12 miles, the second about the same distance,

Digitized by Google

and the third a little less. Before we were many miles out of town we overtook the Protos, stuck in the mud, pulled them out by means of a tow line, and left them.

"After three days' traveling we reached Nikolsk, went on the railroad tracks—although permission had not been accorded

ARRIVAL OF PARADE AT THE CITY HALL

—but when 100 versts further on stripped our bevel gear and had to lie up for repairs. The Protos, coming along slower, received our permit for traveling on the track, and in this way saved itself a long grind through the mud. There were places where traveling on the railroad was good; there were other spots where it was so shaky that I thought my teeth would drop out of my head. The ties were not sunk, but each one raised a considerable distance out of the ground and just wide enough apart for the wheels to drop in between them with a thud and be pulled out again with a jerk. Our first accident happened on a curve where the ties were just sufficiently close together to allow both front and back wheels to drop in together and remain locked. In the fearful wrench which the car received the bevel gear was stripped.

After passing Kharbin, in Manchuria, where we left all the clothes excepting those we stood in, with orders that they should be shipped to Paris, we had some rough traveling, during which we stripped the second speed gear. A spare was telegraphed for, and I went back to Kharbin to get it. It failed to arrive, and I returned to the car to find that in the meantime Miller had put in a couple of stumps to replace the missing teeth. With this makeshift repair we continued, after ordering the spare part to be shipped ahead to Omsk.

"Later our repair broke down, and in order to get the spare part I had to travel 658 versts by relays of teams, a journey that was done in four days by changing teams every 90 versts. There was a reason for the hurry, the Protos then being in our rear, but rapidly drawing up. I wished to get back and make the repair before they caught us, but was not able to do it, the car passing me when I was within but a few miles of the end of the return journey. I reached the car at 1 o'clock in the afternoon; at 4 we were away again.

"At Moscow we were held up for one day by repairs to the clutch shaft, and again, after leaving Berlin, lost some hours along the same repair work.

"When Nijni-Novgorod was reached our difficulties practically ended, for we struck roads that in comparison were so good that we imagined we were on feather beds. We had to pay duty entering Germany, and on leaving the country had to visit three different towns before the amount was returned to us. Ten minutes after we got it we had to hand it out to the Belgian authorities, by whom we were reimbursed on the first request. Finally, entering France on our last day's run from Liege, 1,113 francs had again to be deposited as duty on the car. Getting near Paris we missed the road, and instead of the macadam highway had to travel for a considerable distance over rough granite pave, that cut down our speed considerably. Though there are so many roads to Paris, nobody on the route appeared to know which was the good one. Mein Gott in Himmel! It was certainly a race!"

Subsidizing Automobiles for Army Use.

Subsidies for privately owned automobiles that are kept on a "war footing" compose one of the latest phases of Germany's military enterprise. The German War Office announces that it is prepared to enter into negotiations with manufacturers or private owners for subsidizing their vehicles. To persons with cars answering certain requirements and who pledge themselves to maintain the machines in a condition for military service for a period of at least five years, the following subsidies will be granted: A purchase subsidy for each car, payable upon its definite transfer to the military administration, of $1,000; maintenance subsidies for each car for five years, payable at the end of each year, amounting to about $250; a premium for the use of domestic German petroleum or benzine. The first two clauses refer to cars of 30 horsepower.

LOWELL PLAYS NEUTRALITY GAME

Secures A. A. A. Sanction for Labor Day Race—Fends Off Possible Enmity of A. C. A. Toward Entrants.

When John O. Heinze, president of the Lowell Automobile Club, visited New York a few days ago, in an attempt to secure entries for the Merrimac Valley road race to be held Labor Day, he found that the metropolitan "racing trust," as its press agents now style the several New York dealers, chiefly importers, whom R. L. Morrell and Tom Moore brought together, is anxious to be on both sides of the fence at the same time. Some members of the "trust" wish to compete under the auspices of the A. A. A., and also to curry favor with the A. C. A. As the Lowell race has been sanctioned by the national governing body, the "trust" members suggested to Mr. Heinze that he apply for a guarantee from the A. C. A. that participating drivers would not be barred from future races, run by the local New York club. This he did and, of course, he promptly received the "guarantee."

Following the A. C. A.'s guarantee, several entries were promised for the Lowell event, and Moore was hired to "help things along."

Preparations are being made for oiling the course properly and the grandstand is in course of construction. The race being over a 10 miles circuit and being limited to twelve contestants, is calculated to produce some excitement from the spectators' standpoint.

How Press Agents Earn Their Hire.

In "officially announcing" that Harry S. Houpt has been elected a member of the contest committee of the Automobile Club of America, Mills & Moore, press agents and race promoters in disguise, who apparently have been engaged by the club, this week let it be known that a "racing trust" is "in their midst," and also disclosed how they hope to prove themselves worthy of their hire and to "influence" public opinion. The information was dispensed by Mills & Moore, each of whom is anti-A. A. A. to the backbone, and each of whom has grievances of his own in the form of the following "press sheet" contributed free of charge to the newspapers:

"The fact that the racing trust which controls the Fiat, Stearns, Thomas, Isotta, Allen-Kingston, Renault, and Panhard have decided not to apply to the American Automobile Association for a sanction for the 24 hours race at Brighton Beach, and that the Lowell Club played both ends against the middle in applying for the consent of the contest committee of the Automobile Club of America has caused much discussion among the promoting clubs.

"As the American Automobile Association will be forced to disqualify all entrants and officials at Brighton Beach it will be hard for promoting clubs to get entries for their events unless they resign from the American Automobile Association.

"It is reported that several clubs are desirous of affiliation with the Automobile Club of America. Although the club must be pre-eminent in foreign matters it neither claims nor desires that it shall have any preponderance in the councils of the affiliated automobile clubs."

A. C. A. Issues a Race Resolution.

Following a meeting of the contest committee of the misnamed Automobile Club of America, of New York, this week, the following resolution was reported as having been adopted:

"Pursuant to the agreement adopted at Dieppe by the International Association of Recognized Automobile Clubs it has been resolved that all participants, including the manufacturer, agent, private owner, driver, and mechanician, taking part in any international race in America not sanctioned by the Automobile Club of America will be disqualified from competition in any future races held in this country and abroad."

The resolution, which is specific in its reference to "international races" only, is, of course, in the nature of a stab at the Vanderbilt cup race and although all the paid press agents and the reporters who have been furnished with free admission cards to the New York club's bar, writing room and library, are seeking to make a sensation of it, the resolution is chiefly remarkable as showing that the club still holds true to its foreign inclinations and is striving mightily to fulfill its role as Guardian Extraordinary of Europe's Interests in America.

Why "Racing Trust" Changed Its Title.

The Metropolitan Racing Association, which consists of the several New York dealers and importers whom Bob Morrell and Tom Moore brought together, has dropped "Metropolitan" from its title. Action was taken because the dealers feared that their "racing trust," as their press agent styles the little organization, might be confounded with the fake Metropolitan Automobile Association which consisted of Tom Moore and Mr. Thomas Francis Moore, and which curled up and died after the Motor World turned a searchlight in its direction. Moore's shadow, however, still is behind the "racing trust," whose chief object is to stick in its thumb and pull out more of the plums that are supposed to be in the racing pie. The "trust" believes it best can attain its objects by playing the part of "outlaw" and by promoting "outlaw" races. It doesn't think it requires sanctions from any organization and will make its debut as an "outlaw" organization and as a trouble-breeder generally on the occasion of the meet on the Brighton Beach track, September 18-19.

NINETEEN EVENTS ON THIS CARD

Varied Program from Springfield's Climbfest on Wilbraham Hill—The Course Banked at All Curves.

Nineteen events will constitute the program for the Automobile Club of Springfield's hill climbing contest which will be held at Wilbraham, Mass., on Friday, September 11th. The Wilbraham hill course, which contains some bad turns, has been repaired and the curves banked, and while it is rough enough in spots to insure a lively contest, it is claimed to be one of the best hills for this purpose in New England. The course is 5,280 feet in length, with facilities for a rolling start, and consists of a succession of grades varying from 6 to 23 per cent. The total rise for the measured mile is 453.1 feet, averaging 8.5 per cent., the last quarter dropping from 14.5 to 9.1

The events will be divided into three main classes, to be followed by some special trials. The first class is for gasolene cars, arranged according to horsepower; five different events being scheduled to allow for cars between 15 and 75 horsepower. There also will be a price event, conaestants being divided according to list prices, with six events ranging from $850 to $4,000. The third division of the meet will be forgasolene cars under a piston area classification. Four events, the first for cars under 50 square inches; second, for areas between 50 and 65 square inches; third, from 65 to 90 and the fourth for all cars under 90 square inches.

After these events, which are for stock cars exclusively, have been run off, a trial open to all cars of gasolene power and then an open event for gasolene stock cars, a closed contest for members of the Automobile Club of Springfield, any sort of car eligible, and a second trial for the hill, open to all types and any motive power.

Boosting Good Roads in Utah.

Supplementing a letter campaign to all the voters in Utah, on the subject of good roads and the advantages that everybody would gain by helping along the movement, the Salt Lake Automobile Club has placed an order for 10,000 good roads buttons. The face of the button is made in white enamel with a blue border and the words "Boost for Good Roads" in blue around the edge.

Oldfield the Star at Goshen Meet.

Barney Oldfield was the start of a meet held at Elkhart, Ind., when he set up a new though not remarkable record for the track. Oldfield's previous half mile record for the half mile oval was 1:17¼, and on Saturday he brought it down a hair's breadth to 1:17⅖. Later in the afternoon he defeated Charles Soule in the "Red Spider in a two miles race.

24 HOURS ENDURANCE CONTEST

Bay State Automobile Association Frames Novel Conditions—Run from Boston to Bretton Woods Scheduled.

Boston's big motoring organization the Bay State Automobile Association, has announced a novel 24 hours endurance contest from Boston to Bretton Woods, N. H., on September 23, plans for which have been definitely laid out. The rules framed by the committee in charge, differ to some extent from those followed in the usual style of endurance runs and have been so designed that cars which pull through the run of 375 miles and finish with perfect scores, "will demonstrate their reliability for touring purposes to the satisfaction of any reasonable person."

Contesting cars are to leave Boston at 10 a. m. on September 23, and will be run for 24 hours, not including the time allowed for stops for meals. Motors cannot be stopped without penalization, except at these points, and during the stops no work on cars will be permitted. Changes of drivers will be allowed at controls, if two drivers are designated by the entrant. It is required that observers appointed shall be practical drivers of cars themselves and not "amateurs" lacking knowledge of motors, as was the case with a few of the Glidden Tour observers. The cars will be in two divisions: Class A to include all touring cars, and Class B, the runabouts and roadsters. For every minute or fraction thereof, spent in making adjustments, repairs, or replacements, a penalty of one point will be made. No penalty shall be inflicted for work of any kind done on tires and tire chains, provided the engine is kept running—in case of a steamer, the pilot light may be extinguished while the gasolene supply is being replenished—but the time so spent shall not be deducted from the running time allowed between the various controls. Contestants will be allowed, without penalization, to fill with water, gasolene and lubricant, to turn up grease cups and to oil the machinery, but everything else done on the car aside from the normal operations of starting and of operating, shall involve penalties as above stated. For every minute or fraction thereof during which a motor is stopped, except at Bretton Woods and luncheon points, there will be a penalty of one point. Besides a penalty for replacements on a time basis, there will also be a penalty of a point for each dollar of the catalogue price of the new part. The observers are also expected to make note of other competing cars which may be stopped along the road.

From start to finish every machine must run on a schedule, with penalties for arriving at controls ahead of or behind time. The schedule will allow an average speed between 15 and 16 miles an hour. Cars which lose time at one control cannot make it up going to the next, but must drop back in the line and keep to their scheduled speed.

A suitable certificate will be awarded to each car which finishes with a perfect score. In the event of a single car finishing the run with less penalization than any other car in its class it will be awarded a silver trophy.

A special prize, to be known as the "Observers' award," will be given the operator who, in the opinion of the majority of the observers, makes the most consistent performance, the prize being a gold watch, suitably engraved. Observers will report their choice immediately upon their arrival at the final control.

Success of the Multiple Efficiency Run.

The "multiple efficiency run," recently devised by the Brush Runabout Co., of Detroit, Mich., to introduce the new Model B Brush runabout to the public and to show the car's ability in road work, is being finished this week. Car No. 1, after spending Thursday and Friday of last week in and around New York City, went leisurely to Boston, its final destination, arriving there Monday afternoon. No. 3 got to its destination, Kansas City, a week ago, several days ahead of its schedule. Less time was given to demonstrations during the latter half of the trip than had originally been calculated upon, owing to later arrangements made for it to continue on to Denver, where Mrs. F. A. Trinkle, wife of the Denver agent for the car, will endeavor to drive it up to the top of Pike's Peak.

Cars Nos. 2 and 4, bound for Washington and Minneapolis, respectively, have gone more slowly, owing to a greater number of demonstrations and stops, and the delivery car, No. 5, is nearing Detroit on its homeward trip, after visiting Chicago and Milwaukee and a number of towns in Wisconsin and Illinois. Many of the smaller localities have turned out en masse to welcome the incoming cars with celebrations and entertainments. No very exciting incidents have come to the cars except one slide off an embankment and one case of having the tires slashed by a rowdy in a crowd. The only mechanical trouble reported for all the cars in their journeying has been one defective disc in No. 3's clutch. The interest manifested by the public, particularly in the lesser cities and towns, has justified the company's unique plan of introducing the new model.

Paris to Build Underground Crossings.

Operations are about to be commenced in Paris upon a system of underground crossings at street intersections, the object being to reduce the delays and dangers to traffic and pedestrians incident to the congestion of the crowded sections. The first tunnel is to be installed under the Avenue des Champs Elysees, and the second at the Gare Saint Lazare.

PHILADELPHIA PLANS BIG RACE

Two Hundred Miles Contest for Founders' Day—Permission Given for Use of Fairmount Park Roads.

Philadelphia is to have a 200 miles road race on or about October 7, under the auspices of the Quaker City Motor Club. The meet is to be engineered by the firm of "Jay Kay—Mills & More—Tom; Publicity and Promoting," which is the correct manner of writing this concern's name. Fairmount Park, through which a ten-mile course is to be laid out, will be the scene of the contest and according to the originators of the scheme, the event is designed to "rival of the Vanderbile cup race," which event Messrs. Miller and Moore are using their best efforts to belittle.

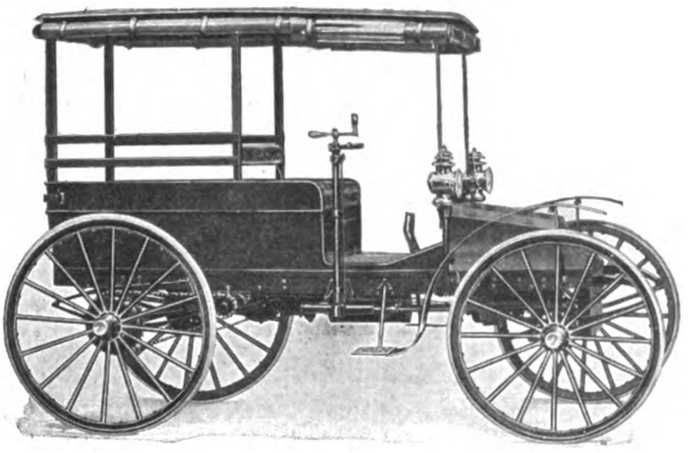
The use of the roads has been requested for daily practice one week before the race, from daylight until 7:30 a. m.

In order to dodge unpleasant friction with either the A. A. A. or the A. C. A., the Quaker City Motor Club has decided to "straddle" and will request a sanction from both the American Automobile Association and the Automobile Club of America. At present there is some question in the minds of the Philadelphians as to whether the three A's will be willing to grant a sanction, for this race, in view of the Vanderbilt contest being so near that date. Should there be a refusal, it is rumored that the promoters will go ahead and attempt to hold the Fairmount Park event as an outlaw meet under A. C. A. sanction, in which case there will be some merry trouble in securing entries.

When the Quaker City Motor Club took up the scheme of holding a road race during Founders' Week, application for a course in Fairmount Park was presented to the Park Commissioners. It seemed a bold move, but aided by Mayor Reyburn and others, the club obtained the desired permission.

The route selected covers ten miles of the finest roads, varying from 40 to 80 feet in width. It is planned to cover this course 20 times. The high bluffs on the river front make a fine natural grandstand, while for those who prefer to watch a score board, a grandstand with a seating capacity of 10,000 will be provided.

Automobile Transport Corps for Army.



After extensive experiments lasting for nearly two years Germany has decided that automobiles may be made to render important service in connection with the army. The budget commission of the German government has decided to report favorably on a bill to authorize a fund of about $500,000 to provide for the organization of an automobile transport corps to be incorporated in the army.

MOTOR DELIVERY ON HIGH WHEELS

Details of Latest Reliable-Dayton—Water-Cooled Motor and Sliding Gear Among Its Noteworthy Features.

Because of the growing strength of the demand for high-wheeled motor buggies, the Reliable-Dayton Motor Car Co., Chicago, Ill., has undertaken the construction and introduction of a high-wheeled delivery wagon, following in principles of design the other vehicles already produced but differing from them in one or two material points. The vehicle in question, which is known as the type "J," has a net load-carrying capacity of 750 pounds, or that of the ordinary horse-drawn delivery. With its 20 horsepower motor, however, its radius is increased to such an extent, that it may be expected to displace from two to three such vehicles without difficulty, carrying out exactly the same service.

The motor is of double-opposed pattern, hung across the frame in front and covered by a removable hood, as in ordinary motor vehicle practice. The cylinders are 5⅛ by 5 inches, bore and stroke and are water cooled. The valves, which are of unusually large size, are mounted with the cam shaft, on the upper side of the motor. The fly wheel is constructed with fan blades to increase the draught through the radiator which is mounted in front and below the level of the hood. Jump spark and battery ignition—both battery and coil being mounted in a single casing on the dash board—positive feed mechanical lubrication, concentric float feed carburetter and geared water pump complete the engine auxiliaries.

The master clutch is of the contracting band type, the same as is used on the passenger vehicles constructed under the same name, is operated by foot pedal, as in pleasure car practice, and is lined with the popular camel's hair friction material. The change gear group is mounted in a unit housing which also includes the differential gearing and a complete housing for the countershaft which reaches to the side frame members, where two points of support for the system are obtained. The gearing itself is of the progressive sliding gear type, mounted on Hyatt roller and ball bearings and affording two forward speeds and the reverse, with direct drive on the higher gear. Final transmission is by outside chains to each of the rear wheels.

The mechanism of control consists of two pedals, one of which actuates each of the two sets of internal expanding brakes, which are mounted on the rear wheels, and a third for releasing the master clutch. The steering control and motor regulating devices are mounted on a control pillar erected at the right side of the driver's seat, the steering gear being actuated through a T-bar side lever, and rack and pinion connections.

Unusually large wheels are employed, the front pair being 40 inches in diameter, and the drivers, 44 inches in diameter. Both sets are shod with 1¾-inch solid tires. The wheel base is 92 inches, the tread, 56 inches, or 60 inches, according to the option of the purchaser. Semi-elliptical springs are employed in front, and full elliptics in the rear, the lengths of the two sets being 36 inches. The body floor area is something over 10 square feet, the width at the bottom being 35 inches, and at the top of the side panels, 46 inches; while the distance from the back of the seat to the tail gate is 44 inches. The total vehicle weight is 1,850 pounds, and the guaranteed load capacity, 750 pounds. In this connection the makers are at some pains to explain that the vehicle is not suitable for trucking purposes, being designed solely for light delivery duty. On that account its strength and speed ratio are figured on a very different basis from what would be the case were heavier duty contemplated.

The form of the ordinary road wagon gives a considerable advantage to the salesman. The class for whom such vehicles are intended are averse to the mechanical problem offered by the full-fledged car.

ORIGIN OF THE PLANETARY GEAR

Principles of James Watt's Invention in Modern Application—Method by Which It is Operated.

It is a curious circumstance that despite the generality of its use, comparatively few motorists thoroughly understand the method of operation of the so-called planetary gear. As a matter of fact, however, it is one of the simplest forms of power transmission imaginable as well as a very old one. Probably it is not commonly known that the inventor of the planetary gear was the inventor of the steam engine, or at least, the one to whom its invention is usually ascribed. As a matter of fact, James Watt, in the famous group of patents taken out during the interval 1781-1785, and covering many of the principles still employed in steam engineering, also protected the invention of the sun-and-planet system of gearing.

Primarily this arrangement comprises merely a central gear mounted on the driving shaft in mesh with a second gear which is carried by an arm loosely mounted in line with the main shaft so that it may swing around it like a crank. A third, and internal gear is mounted on a second shaft in the same axial line, and is of such a diameter as to mesh with the second or planet gear. Three combinations of motion are obtainable with such a system. By clamping all three gears so that they cannot revolve with relation to one another, the system turns as a single part, affording what is known in automobile parlence as the high gear. If the arm carrying the planet gear revolves, the outer or annular gear is made to turn in the opposite direction to the main shaft, and at a slower rate of speed, the planet acting merely as an idler to change the direction of motion. If the annular or internal gear is held fast and the main shaft revolved once more, the planet is made to revolve by the central gear, but as the internal gear with which it is in mesh will not permit it to rotate freely, it is made to travel around inside it exactly as a wheel rolls along a track, the result being that the arm which carries it is turned in the same direction as the main shaft, but at a slower rate of speed.

This principle is employed without change in nearly all forms of planetary transmission, the high, low and reverse speeds being obtained by applying brakes to the planet carriers, the internal gears or the entire group as the case may be. Two or three sets of pinions are commonly employed for greater strength, but the principle is unchanged. In the so-called spur-planetary gears, the internal gear is eliminated while the planet pinion is made to drive a second pinion, on its own shaft, which meshes with a fourth gear on the driven shaft.

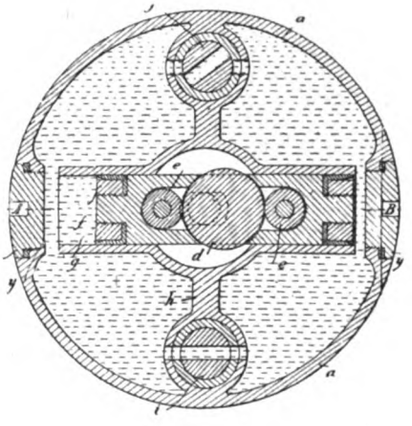
RELEASE FOR EMERGENCY CLUTCH



Double Control Provided for in New Hydraulic Device—Novelty Shown in Method of Construction.

Although it seldom happens that the ordinary types of master clutch in common use are the cause of serious trouble as a result of becoming permanently engaged, this possibility always exists in the mind of the novice, and further, may be realized in the event of failure of any of the connecting linkage between the clutch and the controlling pedal. The idea of providing an extra emergency release entirely independent of the regular means of actuating the clutch would be particularly welcome to a certain class of drivers on this account. With either the cone or multiple disc types of clutch, it is not readily to be contrived. In the Smith hydraulic clutch, which is a British product, distinct provision is made with this end in view. In addition to this, the clutch in question presents one or two rather novel features, which are worthy of attention.

The principle employed is the favorite one with designers of hydraulic clutches in general, namely that of the plunger pump. Two pump cylinders are provided enclosing pistons which are actuated by means of a common eccentric from the driving shaft of the transmission. The inner chamber of the fly wheel in which the mechanism is enclosed, is divided into two compartments communication between them being by means of a couple of openings which are regulated by suitable valves. One of the latter is under direct control of the operator and serves the ordinary purposes of engagement and disengagement, thus furnishing the full control of the vehicle. The other is designed to be used entirely as an emergency cutout, and to be opened by pressing a special emergency lever when the regular mechanism is disarranged, or when, for any other reason, it cannot be used.

The detail construction of the device is illustrated in the accompanying sectional view which is taken at right angles to the axis of the propeller shaft. The hollow fly wheel, a, is positively attached to the crank shaft of the engine, and is internally connected with the transmission shaft by means of the plain eccentric, d, which is operated by the pistons, f, carrying antifriction rollers, e-e, at the contact points. The cylinders, g, are formed in the body of the fly wheel, while the annular chamber formed within the remainder of the enclosure is divided into two sections by means of the partition, h, in which are mounted the two rotary valves, i-j, on opposite sides of the crank shaft.

The interior of the casing being filled with a liquid, the motion of the pistons, when the fly wheel revolves and the transmission shaft is at rest, causes a constant flow of the liquid back and forth through one of the valves, i-j. As already stated, one of these valves may be held closed under ordinary circumstances, but may be opened on emergency, while the other is employed to control the motion of the driven portion of the device. As the controlling valve which may be either of the two, is closed, the resistance to the flow of the liquid is increased in proportion to the reduction in area of the opening in the valve. The effect of this is to reduce the motion of the pump plungers or pistons, simultaneously causing a corresponding motion in the transmission shaft. As the valve opening is reduced this is increased until the valve

is entirely closed, when the circulation of the liquid ceases completely and the entire clutch revolves as a unit—subject only to possible slippage of the pump plungers due to leakage. The device is assembled by means of the plugs, y-y, which give access to the interior of the fly wheel and provide means for the ready removal of the plungers.

Connecting Carburetter and Intake.

When connecting the carburetter to the intake manifold of the engine it should not be necessary to "drift" the bolt holes in the flanges of the couplings in order to bring them into line. If the piping is in good order it should go into place without difficulty. If it does not, it is usually the case that the difficulty may be rectified by altering the position of the carburetter on its bracket. Bringing the parts into line by main force and awkwardness is very apt to strain the joints in the piping and cause leaks.

Little Clips that Should be Tight.

The little clips which are frequently mounted on the outer ends of the long leaves of semi-elliptical springs should be kept drawn up tight and firmly secured at all times. Their purpose is to prevent the leaves from being disaligned and to act as a shock absorber by bringing the outer leaves into action on the rebound, as well as by increasing the friction between the leaves.

REPLACING A CLUTCH LEATHER

Difficulties Encountered in the Operation and How They May be Overcome—Making a Pattern for the Blank.

Drivers who have had occasion to replace a leather facing on a plain cone clutch in nearly all cases have had a more or less unpleasant experience unless they have been instructed as to the proper way of going about it. The cutting and marking off of the rivet holes in the leather are bothersome enough in themselves, but unless they are carefully performed they are not a circumstance to the difficulties which are apt to follow when it is attempted to put the clutch into service. With careful treatment, however, it is possible to secure very good results even without previous experience.

The leather selected for the purpose must be clear, straight grained and of absolutely even thickness. These requirements are absolute. In cutting the blank, it is best to scribe a paper pattern first by laying the clutch disc on the floor or bench upon a large sheet of paper and rolling it carefully along without slipping, marking its path with a pencil until one complete revolution has been made. The leather may then be cut with this pattern, a rather liberal allowance being made for possible inaccuracies.

In applying the leather to the cone it is necessary to stretch it perfectly even and without wrinkling. Further, if it is not started perfectly straight—that is, with its sides parallel to the sides of the cone—it will not run true, but will have to be stretched unevenly to prevent it from working off at one side. On this account it is best to secure it at not more than six or seven points around the circumference, stretching it evenly and choosing points which will not cause it to pucker. Afterward the remaining holes may be easily and quickly put through with a small drill, using the cone as a jig.

The rivets must be headed over carefully so as not to bend them, as in that case the tendency would be to draw the leather. Also they must be driven low enough so that they cannot touch the seating in the fly wheel, thereby causing slipping. After the leather is entirely secured in place, it must be gone over carefully with a sharp rasp or a very coarse file, the edges being slightly beveled and any roughnesses in the vicinity of the rivets taken down, so as to leave the surface perfectly smooth. As a final test of accuracy, the clutch may be assembled and the seating in the fly wheel coated with chalk. When the cone is let into place, the chalk will at once indicate any "high spots." These may be removed with the file, after which the process may be repeated until a perfectly even contact is secured all the way perfectly even contact is secured.

THE HORSEPOWER OF THE HORSE

Churchward Compiles Some Useful Data on the Subject—Where Motor Traction Gains Its Advantage.

Commercial vehicle salesmen constantly are called upon to furnish comparative estimates of the costs of animal and mechanical traction. Generally speaking, it develops in this connection that instead of falling back upon the absolute unit of cost per ton mile of service they are forced to deal with the purely relative and more or less unsatisfactory and misleading statement that the motor vehicle if properly operated may be expected to displace three two-horse teams in the transportation of a given volume of merchandise. For it is a curious fact that even those who are most familiar with the use of horses seldom have accurate knowledge of the costs of horse service in terms of actual paying load hauled and miles covered. Animal transportation, in fact, despite its antiquity is one of the most loosely conducted of modern business undertakings.

For this reason a compilation made by Alex. Churchward, the New York engineer, in connection with his study of motor vehicle work is of particular value. The matter forms a useful addition to the studies of tractive effort and the performance of electric vehicles which already have appeared in these colums from the same source.

That the horsepower of the horse is not the same as the horsepower unit of commercial application is generally conceded. Indeed, there is a tradition to the effect that James Watt, to whom is ascribed the credit of first setting up the contention, purposely set the value of the nominal horsepower at about 50 per cent. above the average output of the normal horse with the laudable intention of increasing the demand for his engine. However that may be it is a fact that few investigators have succeeded in finding horses which could perform the required 33,000 foot pounds of work per minute, and continue to do so except for very brief intervals of time.

According to Rennie, the average work of horses, is 22,000 foot pounds per minute, or two-thirds of the nominal amount of the standard unit. Haswell, however, is authority for the statement that the greatest mechanical effort of an ordinary horse when traveling at 2½ miles per hour is equal to a tractive force of 150 pounds, exerted for 8 hours per day. This reduces to the average rate of 33,000 foot pounds per minute. The more satisfactory method of rating by means of ton miles of duty gives results from which the cost of such service may be computed directly.

From a French experimenter comes the statement that with average conditions of macadam and asphalt, the normal horse can draw at the rate of 2.13 ton miles per hour in winter, and 2.7 ton miles per hour in summer. The average results obtained with the famous Flemish horses of the north of France are 21.82 ton miles per day in winter, and 27.82 ton miles per day in summer, the discrepancy between the results obtainable in the two instances being due to the increased difficulty experienced by the animal in obtaining a good footing on bad roads, perhaps quite as much as on the additional tractive effort required to draw the load over soft ground. From the results of exhaustive tests made at Bedford, England, it was determined that a good horse can draw 1 ton at an average rate of speed of 2½ miles per hour for 10 to 12 hours per day.

When it is attempted to increase the rate at which the work is done, the effect upon the animals, and so the expense is found to increase at an astonishingly rapid rate. Thus, if the cost of transporting one ton of merchandise at the rate of 3 miles per hour be considered 1, it has been proved that at 4.30 miles per hour it is 2, or just double the cost for hauling the same load at about two-thirds the speed.

Another way of considering the same principle is by comparing the possible work of horses in hauling loads both on rails and on hard macadam, at varying rates of speed and for the different lengths of time during which the required amount of effort may be sustained. Results obtained in this way show that the amount of load carried is roughly in inverse proportion to the speed, that is to say that only half as much load can be carried at a given speed as could be carried were the speed only half as great. The accompanying table gives a complete comparison arranged on this basis.

Speed in miles per hour.	Duration of work hours.	On rails, tons.	Macadam, hard, tons.
3.5	11.5	115	14
3	8	92	12
4	4.5	72	9
5	2.9	57	7.2
6	2	48	6
7	1.5	41	5.1
8	1.125	36	4.5
10	.75	28.8	3.6

Coming directly to the tractive effort exerted by the horse, from which an absolute comparison with the work of the motor vehicle may be obtained, it has been found to vary from 300 pounds and over down to 40 pounds, the amount varying with the speed and the length of time during which the effort is exerted. In the following table, two sets of results are compared, one being for efforts exerted at the speeds named for periods of ten hours, or during the whole of a regular working day, and the other, which is credited to Molesworth, for periods of ordinary and short duration. For the sake of comparison they are placed side by side as also casting some light on the probable decrease in the power of the horse when his work is spread over a period of several hours, or to put it another way, as showing the power gained where frequent rest periods are injected into the working period.

Miles per hour.	Tractive effort for 10 hours per day.	Tractive effort for short periods (Molesworth).
.75	330	...
1	250	...
1.5	165	...
2	125	166
2.5	100	...
3	82	125
3.5	70	104
4	62	83
4.5	...	62
5	...	41

The average tractive effort of the commercial motor vehicle is, according to Mr. Churchward's own determinations, somewhere between 25 and 40 pounds per ton on good city streets. For every 1 per cent. grade, 20 pounds per ton must be added to this amount. Comparison between the tractive efforts required on roads of various sorts shows an astonishing increase in the power required for propulsion, which, of course, is the same for a given load, regardless of the source from which the power is derived. Where for asphalt, it may be taken as ranging from 25 to 30 pounds per ton, on macadam roads it ranges from 35 to 60 pounds, and on common earth roads, from 50 to 200 pounds per ton. These considerations are seldom applied to animal traction service, since it is customary to expect the driver to get what work he can out of the horses, and to ignore the effect of highway conditions as having a direct influence upon the life and performance of the animal.

Another factor which is commonly ignored in considering the cost of animal traction, but which is shown by the study of the motor vehicle to be of considerable importance in this connection, is the effect of a number of stops upon the total power output required to transport a given load. Thus, in a previous article from the same source, it was shown that 10 stops per mile increase the necessary tractive effort by 28 per cent. Similarly, 5 stops per mile were shown to increase it no less than 16 per cent. Hence, in animal traction service where frequent stops are required, as for instance the delivery work, it is plain to see that the power output of the beast must be increased in the same proportion, so that increasing the number of stops is roughly equivalent to increasing the mileage.

Though no direct figures are obtainable in this connection as showing the effect of stops and road surface upon horses, a rough indication that the effect is of marked importance is given in statistics of the average useful life of animals under different conditions of service. Thus, the average life of horses hauling a heavy 3-ton truck at an average speed of 2½ miles per hour and from 10 to 15 miles per day, is 7 years. The average horse attached to a delivery wagon making from 12 to 15 miles per day at an average speed of 5 miles per hour lives but 3 or 4 years, before he must be retired.

FACTORY TESTS OF HILL CLIMBING

Jeffery Installs Device Accurately Showing Rambler Capability at Various Grades —Practical Stunts on Inclines.

Mental estimates of hills and grades are much like estimates of speeds, or of the weight of fish that got away, and it is rare indeed that any hill that presents an appearance of steepness begins to equal in cold fact the guesses that are usually made as to its grade. While it is pleasing to the owner of a car to place a very high estimate on the character of some grade which he has triumphantly surmounted, the more sober demands of testing service require that the manufacturer know accurately just what his cars can actually do in this line.

TESTING THE HILL CLIMBING CAPABILTY OF THE RAMBLER

One of the most complete devices to determine the hill climbing powers of automobiles has been installed at Kenosha, Wis., for the use of Thomas B. Jeffery & Co., in connection with the testing system for Rambler cars. As shown by the illustration, it consists of an incline platform and runway. The platform is 25 feet high, and each car, before it leaves the factory, is required to perform a series of hill climbing "stunts" that will prove its ability to do all and more than will be required of it in touring use in the hands of a private owner. After that is being tested is run slowly up the first portion of the incline, which represents a 20 per cent. grade, and then proceeds a little more rapidly up the 30 per cent. grade until it reaches the 40 per cent. section. There the car is stopped and started again on the low gear. Each car is required to climb the full grade on all gears before it passes inspection.

Almost needless to say, the grades are not mere estimates, but were mathematically laid out when the platform was designed. In this way all guess work as to the hill climbing abilities of the machines has been eliminated, and while the runway does not present the picturesque features of many apparently very steep mountain roads, it gives an assurance of fact as to grades, which is valuable to both manufacturer and purchaser alike.

Keep the Fan Adjustments in Order.

If the adjusting device on the fan driving belt is permitted to become disordered in such a way as to render its adjustment insecure, it should be corrected at once, as otherwise there is danger that it may cause the belt to become slack when on the road —a difficulty which will not manifest itself until hill-climbing is encountered, when it may be responsible for serious overheating.

EKING OUT A SCANT FUEL SUPPLY

How a Motorist Made Pebbles Serve His Need—But the Clever Trick Had a Troublesome Sequel.

Being in sore straits as a result of the low supply of fuel in his gasolene tank, an ingenious motorist is reported to have resorted to the simple expedient of dropping small pebbles into the tank, one at a time in order to raise the level of the fuel above that of the outlet pipe, thereby ensuring for himself a very small additional quantity of the needful to carry him to the nearest point where a new supply could be obtained. The device was not without its unhappy after effects, however. For setting aside the clogging effect of the dirt which washed from the stones, it was found to be impossible to remove the pebbles from the tank, even when the tank was taken from the car and shaken upside down. Ultimately it became necessary to take it apart in order to clean it. The incident serves as a good illustration of the need of taking second thought before applying a remedy which results from roadside inspiration, resulting possibly from dim memory of an old fable about the bird that secured a drink by a similar expedient.

SHORT MEASURE ON A SPEED TRAP

How Automobilists Have Been Shaken Down on One Jersey Road—Surprising Results of an Investigation.

Maybe speed traps are desirable as conducing to a more careful observance of law on the part of motorists than would be given were there no such aids to the rural constable and country magistrate. But the bedrock principle upon which any such desirability can be established is that of honesty in their measurement and operation. This appears to be lacking in the case of one or two traps operated between Metuchen and New Brunswick, N. J., and investigation by the legal committee of the New Jersey Automobile Club tends to show that many convictions obtained in the court of Justice of the Peace William H. Housell have been unjust.

On two different days Joseph H. Wood, acting chairman of the committee, accompanied by members of the club and a newspaper representative, went to Highland Park, near which the traps are situated, and inspected closely not only the traps themselves, but the manner in which they were operated. The result was a series of signed statements which Mr. Wood now has in his possession.

The first expedition was made on Sunday, 2d inst. After some search the two traps were found on the main road between Metuchen and New Brunswick, near Highland Park. One trap is operated so as to time vehicles going to New Brunswick, and the other to catch machines running in the opposite direction. A visit was paid to Justice Housell, who holds court in a small white frame house on the western side of the road, and a request was made of the constable to indicate the limits of the two traps. He demurred at first, but at the suggestion of the justice that he comply, accompanied the motorists on the car.

The machine which Mr. Wood drove was equipped with a combined speedometer and trip mileage register, indicating to tenths of a mile. After Constable Mundy had indicated the limits of the traps the car was sent slowly over them and the register carefully watched. On the trap to the north of the justice's place of holding court the distance recorded was correct for the quarter of a mile claimed, but on the trap nearer to New Brunswick was less than the distance was indicated.

After carefully noting the ends of the trap, as pointed out by the constable, the party was about to depart, when a boy was seen signaling with a handkerchief from a clump of bushes many yards in ide the trap. Upon being questioned, he said that he was supposed to wave the handkerchief as a car passed him, as a signal for the man at the other end of the trap to start his stop watch when the automobile passed him at the other extremity of the trap, and if the elapsed time was 35 seconds or less, the second man gave a signal to Constable Mundy, stationed still further down the road, to stop the machine and take the driver before Justice Housell.

The actions of the boy with the handkerchief were carefully watched. It was seen that as several cars went by he waved the handkerchief exactly as the machines passed him, but in at least one instance he waited until the automobile had reached a point several yards beyond him, that is, further into the trap. Both the position of the boy and of the car in the latter instance were noted, and then the party returned to Newark.

On Monday afternoon, 10th inst., another trip was made to the two traps, one of which was found to be in full operation, a motorist being on trial before Justice Housell at the time the investigators arrived. On this day, Mr. Wood had with him not only the witnesses of the previous Sunday, but a surveyor equipped with standard steel tapes. The engineer made a careful measurement of the traps, after the points of location had been found as laid out the Sunday before.

The measurements showed that the trap to the south of the justice's headquarters is four feet short of the 1,320 feet for the quarter mile claimed. The position which the boy with the handkerchief had taken on the Sunday the investigation was made was found to be 106 feet from the end of the trap as pointed out by Constable Mundy, and the position of the car which had been wigwagged after passing the boy was found to be 108 feet still nearer the other end of the trap. This clipped 218 feet off the 1,320 which the course was claimed to be. In at least one case, then, a car had been timed for 1,102 feet instead of the full quarter of a mile.

This difference is sufficient to cause an apparent increase of speed of five miles an hour over the actual speed. For instance, if a car were traveling at such a rate that it made the 1,102 feet in 30 seconds, it would actually be traveling 25 miles an hour. This is a speed at which Justice Housell asserts he has never convicted a motorist, holding that a margin of five miles per hour above the limit of the law should be allowed for errors. According to the computation for a full quarter of a mile, however, the machine was making 30 miles an hour, and its driver would certainly be convicted.

Moreover, according to the voluntary statement of Constable Mundy, motorists are fined if they cover the distance of the trap in 35 seconds or less. Figuring on the speed for 1,102 feet at 35 seconds, gives only 21 miles an hour, an excess over the limit of 20 allowed by the law, which no judge would recognize. How many motorists have been fined through the "mistake" in measurement cannot be determined.

LOWERING THE "BISCUIT RECORD"

Grain Harvested, Ground, Made into Bread and Eaten within 22 Minutes—How an Automobile Assisted.

Waitsburg, away out in Washington, is proud! It has placed the "biscuit record" to its credit and owns up that the automobile made it possible. The story of the glorious achievement is thus heralded by a Washington correspondent:

"Dale H. Preston, driving a 30 horsepower Corbin automobile, sent over a quarter mile stubble field and 1¾ miles of country road at a 70-miles-an-hour clip, was the chief factor in lowering the world's record in producing biscuits made with flour from the plump heads of grain which nodded in the morning sun 22 minutes before. The feat was performed at Waitsburg, Wash., south of Spokane, the grain being grown on a hillside farm owned by N. B. Atkinson, president of the Washington State Farmers' Educational and Co-operative Union, two miles from town, and the test was witnessed by R. M. Breeze, mayor, and 50 residents.

"The various stages of the operation and time announced by R. H. Ormsbee, formerly prosecuting attorney of Walla Walla county; E. L. Wheeler, editor of the Waitsburg Times, and Platt B. Morrow, general merchant, official time keepers, follow:

9:03—Ripe wheat standing in the field.

9:04—First head clipped from the straw by the heading machine.

9:08—Grain started into the cylinder of the threshing machine.

9:11—Four sacks threshed, sacked and sewed and loaded onto automobile.

9:14—Grain received at mill, two miles from field, weighed and dropped into the receiving hopper; four sacks weighed 535 pounds.

9:19—First flour appeared at packer, having traveled 640 feet in the machinery. A. Beck, baker, began mixing flour, baking powder and water into dough.

9:21—Molded dough in pans placed into oven.

9:23—Two sacks of flour ground, sacked and sewed, ready for market.

9:26—Biscuits taken from the oven, buttered and distributed among witnesses.

"With the exception of the automobiles employed to carry the grain and the time keepers and the pressing into service of a gasolene oven, the process of harvesting and manufacturing was regular, the cutting and threshing being done by an ordinary crew, which had operated the machines in the field two weeks."

The broad asphalt pavements of Washington are to be sprinkled by automobile water wagons. No demands have been made by Washington's floating population that passenger arrangements be provided.

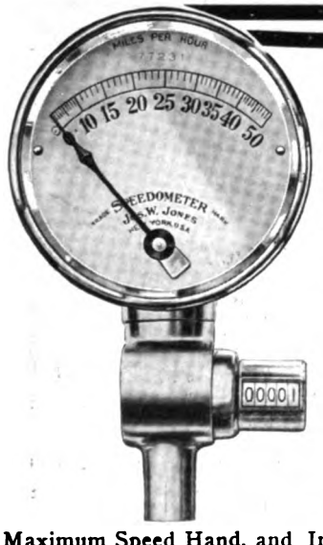
SUPPLEMENTARY SPIRAL SPRINGS

¶ If every driver had to ride in his own tonneau, every car would be quickly equipped with Supplementary Spiral Springs. Owners are not intentionally selfish—many of them just thoughtless. Usually driving or sitting beside the driver, the riding qualities of the tonneau are to them practically unknown.



¶ Not so with the passengers. Rear springs must be strong enough to resist severe shocks under a full load. That means stiff springs under ordinary loads, with the shocks and jars transmitted to the passengers—guests whose comfort ought to be a first consideration.

¶ **SUPPLEMENTARY SPIRAL SPRINGS** take up all the average bumps and road inequalities and come into real action with the jolts and jars encountered at speed.

¶ With the S. S. S., your springs never whip or touch. They prevent breakage and are the most economical and useful accessory ever provided for a car. Every live dealer carries them and their attachment is a matter of a few hours' time. Do it NOW.

SUPPLEMENTARY SPIRAL SPRING CO.

Motor Mart, New York — 4555 Delmar Ave., St. Louis, Mo.

THE BEST Speed Indicator in the World for $25

JONES SPEEDOMETER

The Jones at $25 actually excels in accuracy and efficiency, instruments sold by other manufacturers for $40 and $75. This instrument has 3-inch porcelain dial, 50-mile speed scale, 10,000-mile Veeder Odometer register. Same driving mechanism as Jones Standard instruments.

The Jones with the exclusive Maximum Speed Hand, and Instantaneous Reset Odometer is beyond competition. It is the acknowledged Standard speed indicator of the world.

Out of 46 contesting cars for Glidden and Hower Trophys and Glidden Certificates, 33 cars were equipped with Jones. 4 out of 5 Official cars also carried Jones.

Write for "The Speedometer," a magazine devoted to speed subjects, and the Special Speed Issue of "The Evening Bulletin" of particular interest to all motorists.

TO DEALERS AND AGENTS

¶ Have you given thought to the manifold, unusual, good qualities of the

Gyroscope Car

¶ The merits of the car are so pronounced that we have contracted for the ENTIRE OUTPUT of the Detroit factory for FIVE YEARS.

¶ At $750, equipped, the Gyroscope Runabout, or at $800, the Tourabout or Touring car, is by far the best selling proposition of the times.

¶ Its freedom from cranking, its absence of transmission annoyances, its anti-skid feature (due to the gyroscopic action of the horizontal fly-wheel), its low cost of maintenance, elimination of vibration, and the impossibility of turning over on short curves at high speed, and its minimum wear on tires, combine to make the GYROSCOPE Car the safest, simplest and most economical car ever put on the market.

¶ We are signig contracts daily for territory allotments on better terms than other companies can afford to offer. There are no conditions (such, for instance, as making you sell higher-priced cars to get your small ones). By November 1, we shall have closed for our 1909 output.

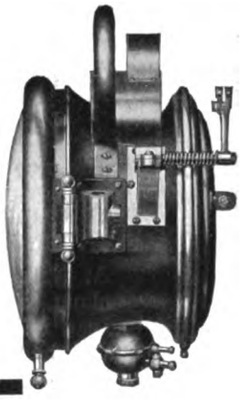
SOLARCLIPSE LAMPS

THE WONDERFUL SOLARCLIPSE LAMP



throws two distinct rays: one powerful long distance field of light—and one short distance. The first is thrown over one thousand feet ahead—the second directly in front of the motor car.

It is generally admitted that the blinding glare from a Headlight or "Search" impairs the usefulness of the lamp, when city driving is necessary.

The Automatic Self-Eclipsing Mechanism

makes it possible to suppress the long distance ray at will—this leaves the road immediately before the car brilliantly illuminated. Solarclipse Lamps completely solve the acetylene head light problem.

Complete description of this wonderful lamp in our 1908 catalog, sent free upon request.

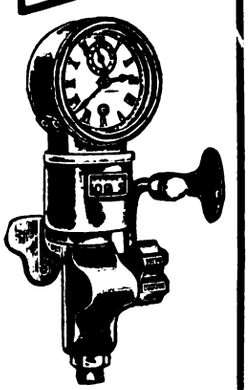
WEED CHAINS

Made Perfect Scores Possible in the Glidden Tour

Had it not been for Weed Chains it is doubtful if any of the cars in the Glidden Tour would have completed the 1,669.7 miles run with perfect scores.

Mrs. Cuneo's telegram says: "Used chains three wheels; hardest day's trip 130 miles, over mountains; record time an impossibility without chains." This makes clear that it would not have been possible to travel on the wet, slippery roads without the use of Weeds.



Weed chains when attached to your tires positively prevent skidding. They grip and hold the wheels to the road, and enable the heaviest automobile to climb hills, or negotiate in mud or sand without any trouble. They prevent lost traction, and reduce gasolene consumption. Fit any standard tires; are readily attached and detached.

Write for "THE WEED," a Bulletin.

Warner Auto-Meter

GUARANTEED FOR ONE YEAR.

"Thirty Days' Free Trial"

When a manufacturer is willing to send his product to anyone, anywhere, for 30 days—with no deposit, no agreement to buy, no promise to do anything except give that product a fair trial—he must have more than ordinary confidence in his article. In order for him to have that confidence he must have a most extraordinary product.

That's what we do. We'll send an Auto-Meter to any automobile owner in the country—with no deposit, no agreement, no promise to do anything but put it on his car and give it a fair trial. It doesn't matter whether he has another make of speed indicator already on the car or not. Indeed, for the sake of comparison, we hope he has. We will abide by the decision—for he will always keep the indicator that tells the truth. We claim for the Auto-Meter that it is the only one of which "the dial never lies." We believe that the instrument itself is the most eloquent salesman we have—we're willing to let it do our talking. Send to-day—just tell us what make and model of car you have—size of tires, etc.,—and we will send you an Auto-Meter.

The Week's Patents.

888,906. Cushion Tire. James B. Jordan, Nashville, Tenn. Filed Feb. 25, 1907. Serial No. 259,181.

1. A vehicle tire comprising a hollow, heart shaped resillient core, a cover therefor, combined with means for securing the core and covering to the felly of a wheel, and cloth-covered metallic inserts in the tread of the cover to prevent slipping and skidding of the tire.

888,932. Automobile Sled Attachment. Henry H. Rohlf, New London, Wis., assignor of one-third to Adolph L. Haase, New London, Wis. Filed Sept. 9, 1907. Serial No. 391,985.

1. In combination, a runner, a driver mounted upon the runner, a jack interposed between the driver and runner to effect certical movement of said driver, said jack comprising a cylinder and a plunger, and means for supplying a fluid medium to the cylinder of the jack to effect movement of the driver.

888,933. Traction Wheel. Henry H. Rohlf, New London, Wis., assignor of one-third to Adolph L. Haase, New London, Wis. Filed Sept. 9, 1907. Serial No. 391,986.

In a traction wheel, the combination of a rim comprising a felly and a tire, the same having registering openings, the openings in the tire being internally threaded and the openings in the felly being contracted, cogs, each consisting of a tapered end, a threaded body portion and a stem having its outer end threaded, a shoulder being provided at the base or juncture of the body portion and pointed end, said cogs serving when in position to connect the tire and rim and having their shouldered portions engaged with the tread surface of the tire, their threaded body portions screwed into the threaded opening of the tire and their stems passed through the contracted openings of the felly, and set nuts fitted upon the threaded ends of the stems.

888,965. Automatic Carburetter for Explosive Motors. Louis M. G. Delaunay-Belleville, Paris, France, assignor to Societe Anonyme des Automobiles Delaunay-Belleville, St. Denis, Paris, France, a Corporation of France. Filed Sept. 30,1907. Serial No. 395,205.

1. A carburetter comprising a casing having a tube for the passage of vaporized fuel and primary air, a supplemental air inlet in alignment with said tube, and a conduit extending laterally from said tube, means arranged at the junction of said tube and conduit for deflecting the vaporized fuel and primary air from said tube and the supplemental air from said inlet into said lateral conduit, and a device for controlling in direct proportion the quantities of vaporized fuel and primary air, and the supplemental air admitted to said inlet, into said conduit.

889,069. Pneumatic Tire. Charles E. Titus, Springfield, Mass. Filed June 21, 1907. Serial No. 380,136.

1. A tire reinforcement comprising a plurality of overlapping and interengaging tread members connected to the periphery of the tire and having the central portion of its lower face constituting a fulcrum.

889,181. Transmission Mechanism. Orson W. Davis, Rochester, N. Y., assignor, by direct and mesne assignments, to Gearless Transmission Co., Rochester, N. Y., a Corporation of New York. Filed Oct. 24, 1906. Serial No. 340,354.

1. In a transmission mechanism, the combination of the motor and driven shafts in axial alignment and independently rotatable, of means mounted upon said shafts and rotatable therewith for connecting them to cause them to turn in unison, and frictional transmission members some of which are supported independently of said shafts, and others of which are mounted on said shafts for connecting said shafts indirectly to drive the driven shaft in either direction at a speed different from that of the motor shaft.

889,263. Pneumatic Tire for Vehicle Wheels. Robert P. Scott, Cadiz, Ohio. Filed June 20, 1906. Serial No. 322,552.

1. The combination of a pneumatic tire having an inextensible selvage, a flanged rim carrying an expansible band furnishing an adjustable seat for the selvage, and an annular, expansible and removable side flange, sprung into the space between the band and rim flange to hold the inflated tire in position, substantially as described.

889,334. Armor for Tires. Frank E. Remark, Akron, Ohio. Filed Nov. 21, 1906. Serial No. 344,484.

A chain armor for tires formed of a plurality of rows of links circumferentially disposed with respect to the tire of the wheel, each of the links of said rows of links substantially rectangular in contour and having rounded corners, the end portions of each of said links bent above the plane in which is positioned the intermediate portion, each of the links of each row with the exception of the links of each outer row interlocking with four adjacent links, each of the links of the outer row interlocking with three adjacent links, said links gradually increasing in width and length towards the center of the armor.

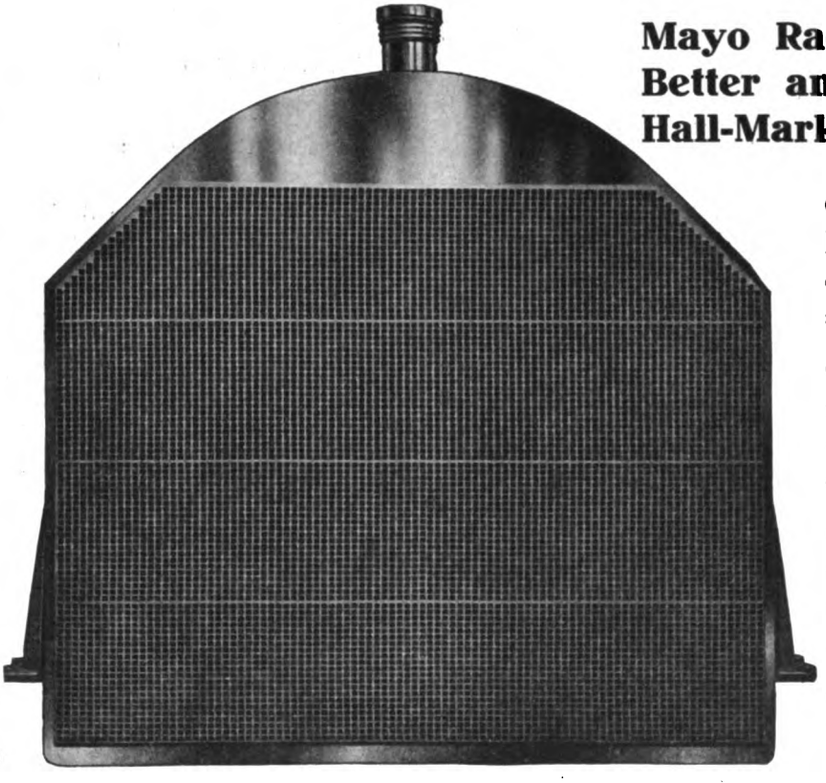
DOW TUBES Are the Most Economical

(The Best Tubes Ever Manufactured)

ONE YEAR'S CONSTANT SERVICE IN THE BOSTON FIRE DEPARTMENT

Dow Tire Co., New York, N. Y. Headquarters Fire Department, City of Boston, Bristol Street, Boston, July 20, 1908.

Gentlemen—Having used the Dow Non-Deflation Tubes since August 19, 1907, on the automobile used by Chief Mullen of this city fire department in his response to alarms of fire, I feel that, in return for the excellent results received from these tubes, I ought to inform you of same. Several persons have inquired of me as to their merits, and I have always spoken in the highest terms of them, but never felt that I could write you confirming my statements until such time as they had been in use for about a year.



We have given them all kinds of tests, and will truthfully say that they have withstood all punctures, and with the exception of "blowouts," which are liable to occur with any type of inner tube, they have given excellent satisfaction.

Trusting this letter may be of benefit to you, I remain, Yours very truly, (Signed) JOSEPH A. WEBBER, Lieut., Aide to Chief.

"Whitney" 1909 Model Chains and Prices

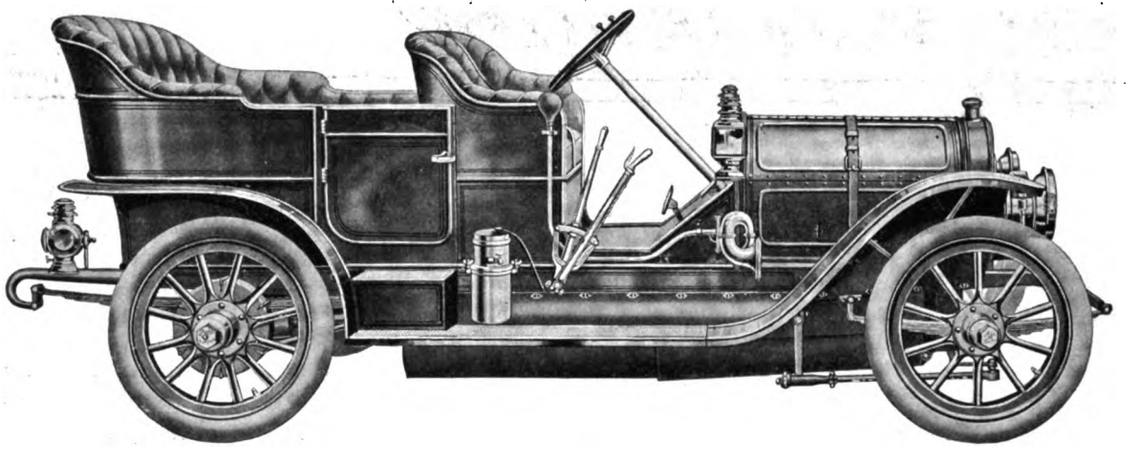
ARE NOW READY

All Motor Car Manufacturers should get full particulars before closing, as we have made great gains in strength and durability. With certain sizes of chain we have gained over 100% on earlier models.

New "Whitney" Chain Belt
FOR
Cooling Fans, Oiling Devices, Motorcycles, Etc.

If you are not taking advantage of the Woodruff Patent System of Keying it will pay you to investigate.

Better results and a great saving in cost.



We carry 95 regular sizes of Keys and Cutters in stock for immediate delivery.

1909
Pope-Hartford Models

Pope-Hartford Model S, $2750

The POPE-HARTFORD 1909 models embody all that is best in automobile construction and will be conspicuous in the foremost ranks of the automobile world.

We invite comparison of the details of POPE-HARTFORD cars for 1909 with those of the world's best motor cars. Because of their perfection, refinement and elegance they will appeal to the superior judgment of critical and discriminating purchasers.

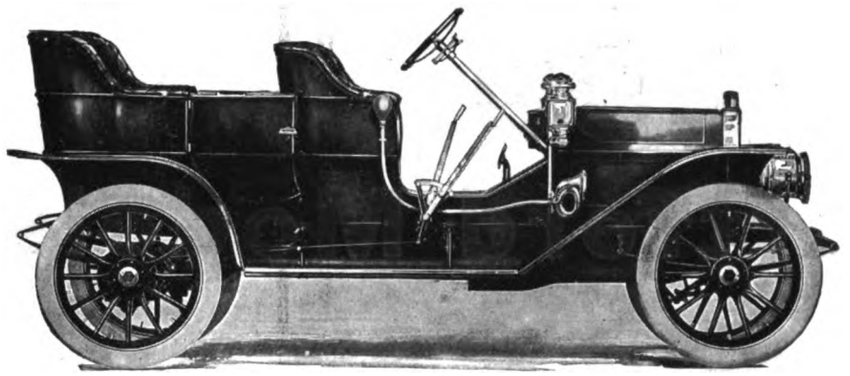
OUR 1909 LINE WILL CONSIST OF THREE MODELS:

A Standard Touring Car similar to the above illustration, **Price $2750**

A Standard Roadster which will be illustrated in this space next week, **Price $2750**

A Pony Tonneau Car which will be illustrated the week following, **Price $2750**

New and important improvements, not incorporated in any other motor car, are included in the POPE-HARTFORD 1909 CARS. Each improvement which we have added has been given a careful and thorough *test,* and our catalog, now in preparation, explains fully all the details and mechanical excellence of the new models. Let us place your name on our mailing list for an advance copy.



Agents almost everywhere. Correspondence invited with interested dealers.

E-M-F "30"

TOURING CAR $1250

THE NEWS

On June second at a dinner at the Cafe des Beaux Arts, New York, the organization of the million dollar Everitt-Metzger-Flanders Company was announced.

Today—less than three months from that date—this "hyphenated" concern is rated one of the biggest factors in the automobile industry.

The interest created when the personnel of the company was announced was increased to a veritable sensation when the specifications of its product, the E-M-F. "30" Car, were given to the world; and when the price for this splendid car, with full lamp equipment and magneto, was set at $1250, there ensued a small sized panic among the high-price contingent of automobile manufacturers—and those who thought they knew how to manufacture, but try as they would, were unable to see how we could do it at the price.

Of course we have their sympathy—we are sure of that.

We also have their advice—in chunks. "Raise the price to $1500—you'll sell all you can make," is the burden of their fatherly promptings.

Still we don't heed—don't even realize that we are on the very brink of destruction or that we are "throwing away a million or so" by selling a car at $250 to $500 less than any other concern ever has or can sell a car of equal merit.

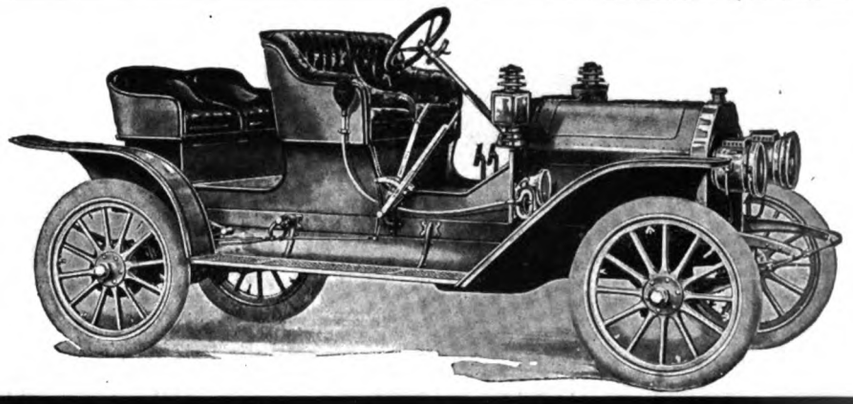
You who read this have doubtless kept in touch with the development of the automobile industry during the past ten years. If so, you can recall that each successive year there has appeared some one car that possessed all the earmarks of success—that seemed to represent the highest state of development up to its time. And you recall that, with unerring instinct, that car sprang into instant favor with the trade and public alike.

Well the E-M-F. "30" has taken at a bound, and today occupies, that enviable position.

It is admitted leader—makers of cheaper cars are already saying "Just as good as the E-M-F. "30," while those whose product is listed a few hundred dollars higher, are busy explaining why. And without much success for a comparison of the product—details of design, materials and workmanship—shows the E-M-F. "30" to be incomparably superior at every point.

There is a reason: The men back of the E-M-F. Car have a standing in manufacturing circles that guarantees the excellence of product. And the car itself combines so many features every motorist knows to be the best, all agree it is a composite of superiorities.

Each man who examines the E-M-F. "30" or reads the specifications feels as if he had designed it himself so nearly does it approach his ideal in every detail, his heart's desire as a whole.



We believe that to the man who has not seen and ridden in an E-M-F. "30" Car, or to one—if any such there be— to whom a mechanical description conveys no clear idea, the names of the men—financiers, manufacturing experts, sales and advertising specialists—back of this product is a guarantee not only of quality in the car, but of conscientious, generous treatment to the buyer afterward.

That's why we lay so much stress on our organization; so much that envious rivals have dubbed us "The Mutual Admiration Society"—a compliment we accept cheerfully and gratefully; for ot not all organizations can this be said. It's a factor that makes for concentrated effort and guarantees results that are unobtainable by any organization where this same mutual confidence and admiration are absent.

Digitized by Google

E-M-F "30"

ROADSTER $1250

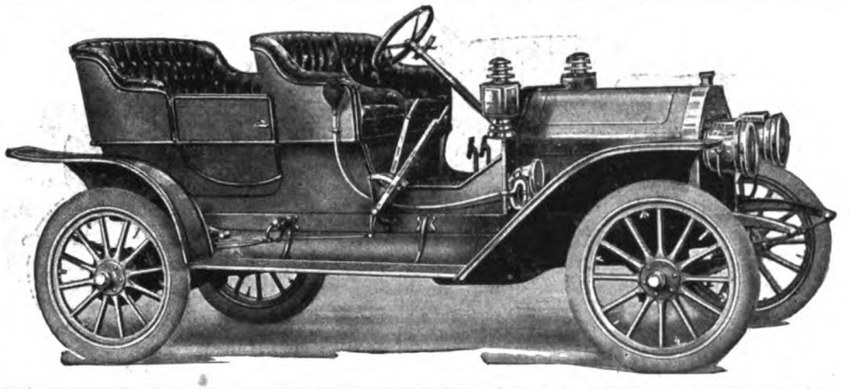
THE ORGANIZATION

First: The capitalists back of the E-M-F. Co. They are not tyros at the game. All are men of ripe experience in the business. All have been connected with it from its infancy—learned to know it in all its phases and caprices. Being young men they have optimism plus and a faith unfaltering in the future—the far future of this industry. They don't ask, don't desire, big dividends the first year. They have a pride in the product, a desire for success on broad lines—an ambition to excel. They are willing to forego the mushroom profits of today in order that a foundation may be laid, a policy formulated, that shall meet all conditions and stand the test of time. But money alone will not build automobiles. Capital unaided by experience, cannot cope with manufacturing problems.

Organization—a merger of brains and experience—is essential to success on a large scale. This fact was fully appreciated by Mr. B. F. Everitt, organizer, and president of the E-M-F. Company. In "framing up" his company he determined on an "all-star cast."

Until a few months ago, one of the largest manufacturers in the accessories field, Mr. Everitt's acquaintance with the men who did the things other men got credit for, eminently fitted him to select the right material. The result is a group of men every one of whom is a specialist—an acknowledged leader—in his own line. All have made good to a signal degree—the history of the industry is their history—the credit for its greatest achievements, theirs.

Than William E. Metzger, Secretary, and Sales Manager of the E-M-F. Co., no man in the motoring world is better or more favorably known. As Sales Manager of the Cadillac Automobile Co. from its inception, he has run the whole gamut of experience, taken a prominent part in every event of any importance, held many offices, been the receipient of many honors. The name Metzger stands for a broad gauge policy, a concrete sales organization, and to the buyer of E-M-F. cars ensures liberal treatment, at all times.



If, as all authorities agree, the future is to the concern that can produce on the largest scale, most accurately, most regularly and economically, then Walter E. Flanders is the very keystone to the arch of the E-M-F. organization. He is recognized as the greatest factory organizer, the keenest buyer, and by far the ablest producer the industry has known. As Manufacturing Manager of the Ford Motor Company until a few months ago, his record is patent to the world—it yet stands unequalled—unchallenged.

Back of Mr. Flanders are Factory Manager Thomas Walburn, General Superintendent Max Wallering and the several department heads—forming an "officers' mess" in which perpetual harmony prevails, because each is a specialist, an expert in his own line and none conflicts with another. It is only with such an organization that great things are possible.

Chief Engineer Wm. E. Kelly has been in the business from its infancy—he antedates some of the "pioneers" who make greater pretentions. Like others he has designed some cars that did not come up to his expectations—in later years by riper knowledge he has produced some of the very best. In the E-M-F. "30" Kelly and his corps of designers have realized a long cherished ambition.

E. Le Roy Pelletier, formerly Advertising Manager of the Ford Motor Company, is known by his work—and its results. In fact, there isn't a weak link in the chain—no man of mediocre ability filling an important position—no deadwood anywhere.

E-M-F "30"

DEMI-TONNEAU $1250

THE CAR

Nothing added—no frills or furbelows. Nothing omitted that experience has proven or convention taught you to consider a necessary part of a first class motor car. Not one original feature—not a single novelty—no startling innovations. Not one experiment—not one hair-brained theory or half baked mechanical idea; not an untried invention—or metallurgical hallucination—will you discover in the E-M-F. "30."

Instead you'll find all the good, the simple, the reliable features you have come to know as standard.

In the early days there may have been some excuse for the maker trying out his inventions, his theories, on the buyer—at the buyer's expense. But today we know what details of construction go to make up a first class automobile— the wise manufacturer is the one who combines these rather than tries to invent new ones.

The motor is the accepted standard 4-cylinder verticle, four-cycle type—well built, with large valves, silent and smooth in operation. A magneto is a part of it—as it should be—not an extra.

The sliding gear transmission is superior to any other known type; and ninety per cent. of buyers prefer the "selective" system of operation. These are combined in the E-M-F. "30" in a little neater, a little more compact form than in any other car. The operating system is very nearly ideal.

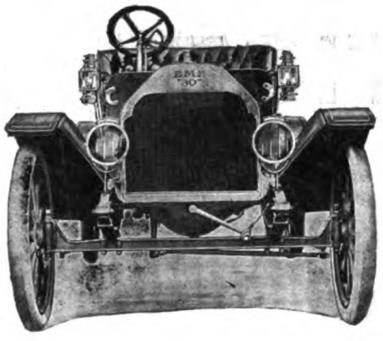
It's admitted that the "unit" system of power transmission is ideal—transmission and rear axle in one; but it has been considered too expensive for any but high priced cars. You'll find it in the E-M-F. "30" in the neatest, lightest and most compact form.

The brake system is the best known—four brakes all acting on rear hub drums.

The steering gear is of the worm-and-sector type, identical in design, material and construction with what you'll find in cars of $4,000 to $5,000—simplest as well as best.

Of coil, radiator, commutator and all other parts the same holds good—they are the best types you know.

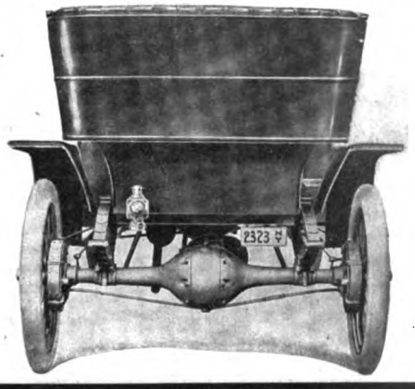
A magneto has, hitherto, been considered only as a part of a high priced car—and then as an expensive extra in all but a very few cases. It is as much a part of the E-M-F. "30" as are the valves. We believe a constant, uniform and absolutely reliable source of electrical energy is essential to pleasurable motoring. We've set the pace for all makers by building the magneto into the motor and including it as a part of the equipment without extra charge. Other cars listed at prices to compete with the E-M-F. "30" figure more nearly $2000 when equipped with magneto, lamps, top and other touring necessities.



The E-M-F. "30" is not an "assembled" job. We make every part of it in our own factories.

The day of the "assembled" car has passed. An automobile is too complex a piece of mechanism—requires too accurate a degree of workmanship on every part, to lend itself to the methods of parts makers and assemblers. We speak by the book, having had extensive experience in the "assembling" field.

Makers of "assembled" cars have our sympathy; buyers of them our commiseration.



So long as motor, axles, transmission and other vital parts are farmed out to different makers, accuracy is absolutely impossible,—interchangeability unobtainable. And the failure of a parts maker—or a discontinuation of business relations between him and the concern who furnishes the nameplate—leaves the owner in a helpless, hopeless position.

E-M-F "30"

BEFORE AND AFTER

THE WHY AND THE HOW

Since the price of the E-M-F. "30" Car announced, this subject has been up for discussion—and criticism—in no less than two manufacturers' meetings, to say nothing of the countless informal gatherings of trade gossips where it has been the chief topic of discussion.

"Why," they ask, "why give the public a million dollars and more on your first 5000 cars (they all protest we'll raise the price so soon as the reputation of the car is established) by selling such a car for $1,250 when, goodness knows, you can sell all you can make at $1,500, or a few hundred dollars more for that matter? Why set the price so low?"

"In order to increase the quality," we answer.

They don't understand—and yet they claim to be manufacturers.

Here's the explanation—its obscurity lies in its very simplicity.

A better car can be manufactured and sold for $1,250 than is possible at twice that price. Mull that over.

There's no catch—no play on words. It means exactly what it says. And here's why:

For every man who can afford a $2,500 car there are 500 who can afford one at half that price—500 to 1!

Figure it out: statistics prove there is only one man earning $5,000 a year for every 500 who earn $1,800—and, whereas, no man with an income less than $5,000 can afford a $2,500 car, a $1,250 car should not be considered a luxury for a man earning $1,800 a year.

Certain of our market, we can plan on a large scale—12,000 cars in a year. Buying for this quantity we get the lowest price on raw materials. Manufacturing in such quantities we are able to adopt the most modern methods and to install highly specialized machinery. We cut the cost of production in half. And we increase the quality at the same time because methods are possible to us that no maker of $2,500 cars—producing in the small quantities the limited demand permits—can adopt.

Here's one example that illustrates why:

The cost of dies for making one part of the rear axle of the E-M-F. "30" Car is $9,000. Suppose the output be only 100 cars of this model—the "overhead" on that part would be $90 in each car. Carry the same practice through the entire car and it couldn't be sold for $20,000! On 1000 cars it would still be prohibitive—$9.00 per car. On 2,500, which some "name plate" manufacturers call "large quantities," it still figures $3.60 for tool cost on only one of over 1,000 parts in the car. On 12,000 cars it amounts to the insignificant sum of 75 cents per car. And the part is absolutely interchangeable—lighter, stronger, better in every way than any similar part has been made before in cars of the highest price. Of course not all items reduce so rapidly, but throughout the entire car the saving is more than half.

In giving the buyer the full benefit of this saving we do not pose as philanthropists—we are merely making sure of our market without which the manufacturing of 12,000 cars would be a risk no sane concern would venture to assume. The price makes the market—the ready market makes quantity production safe—quantity production makes the price possible. It's as complete as a circle and as simple.

Send for detailed information and specifications.

EVERITT-METZGER-FLANDERS COMPANY, Detroit, Mich.

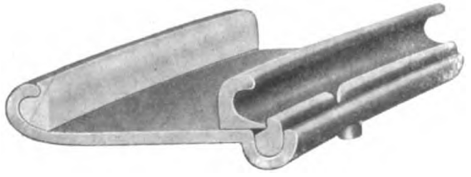
DID YOU NOTICE

that all the E-M-F. 30 cars will be fitted with

MORGAN & WRIGHT TIRES

as a guarantee that the tire equipment shall be above criticism.

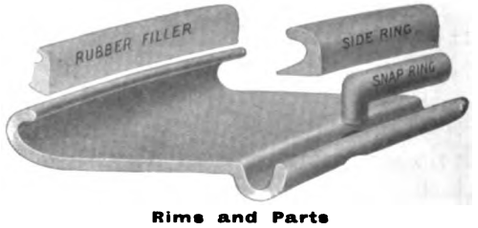


There is no method of making friends equal to the method of making good

For Clincher Tire

The Standard Universal Quick Detachable Rim

As an evidence of the favorable impression this rim has made upon car manufacturers, it may be stated that it has been adopted by the Association of Licensed Automobile Manufacturers as standard equipment for American cars; the change to take place as soon as it can be conveniently arranged.



For Dunlop Tire

Removed and applied by simply unsnapping or snapping the locking ring. No turnbuckle to bother with.

Accomodates any standard size tire, Clincher, Dunlop or Quick Detachable.

Morgan & Wright Tires and Standard Rims would furnish a matchless equipment for your car, from the standpoint of both economy and modern rim design.

Rims and Parts

$2000

THE SELDEN CAR

Finished the Glidden Tour with a CLEAN SCORE and Was Deprived of a "Perfect Score" by a Technicality

We entered a stock car, which had already been run over 5,000 miles, without any shock absorbers, straps, bumpers or other safety appliances, complying strictly with the rules as to equipment. (All other cars were equipped with these devices.)

Our car was equipped with a speed indicator, the sprocket connection of which worked loose crossing the mountains in Western Pennsylvania and fouled our steering knuckle, making it impossible to avoid a large boulder in the middle of the road, and we broke a front spring in consequence.

The broken spring did not penalize us, nor the repairing of the spring, but because we used four machine-made nuts (instead of four hand-made nuts) we were disqualified from further contest for the Glidden Trophy.

Our car continued the tour as a non-contestant, checking in and out every day, observing all the rules and finished with a clean score.

It was in such good condition upon arriving at Saratoga that we made a non-stop run from Saratoga to Rochester, a distance of 272 miles on the following day without any adjustment whatever.

Our "extra parts" bag was not opened on the entire trip. No other car did any better.

COMPARE OUR CAR WITH OTHERS IN THE TOUR AND SEE WHAT WE HAVE ACCOMPLISHED

Demonstrating the highest quality of workmanship and material, durability, stability and the all-important fact that a strictly first-class gentlemen's car can be made and sold for $2000.

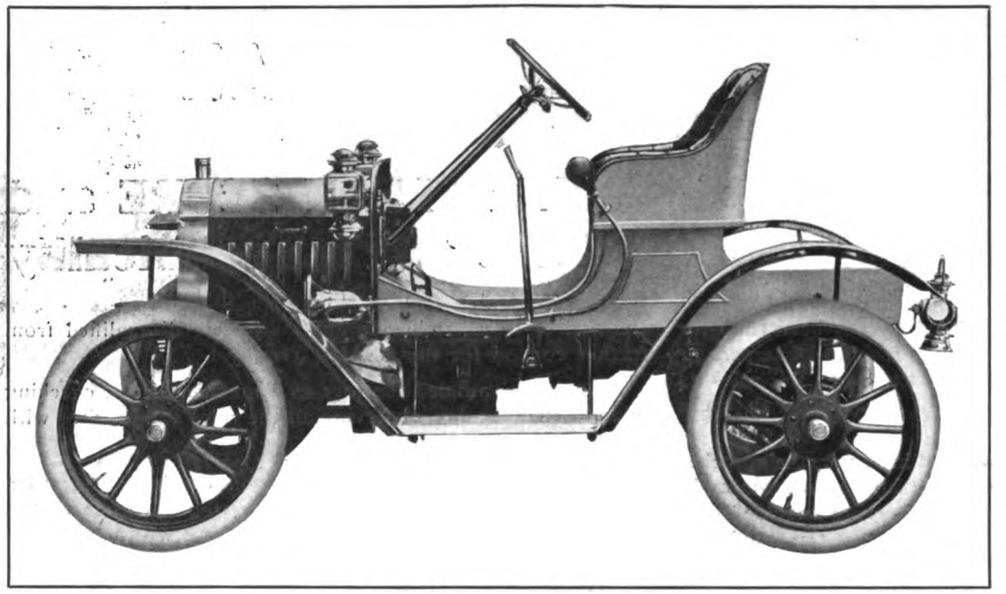
Why Pay Double the Price for a Name-Plate?

Duplicates of this car are now ready for delivery.

All our cars are sold with a guarantee and with all that we have out during the past season the cost of repairs amounts to little or nothing.

The "Silent Selden" (as the car has become known by its quiet running) is made on honor, a credit to the name of the man who invented gasolene automobiles, and every owner is proud of his purchase.

Superb riding, roomy tonneau, luxurious upholstery, smooth running, great hill climber, flexible and easily handled, economical in up-keep, stylish and attractive—the coming car of the multitude.



Now closing 1909 agencies—over half our output already spoken for. Good live agents wanted everywhere. Send for catalog and agency proposition.

SELDEN MOTOR VEHICLE COMPANY, Rochester, N. Y.

DEALERS—We Are Delivering Now

Model B

BRUSH Runabout

$500 - $550

While waiting for the wonderful things to happen next month or next year, we advise you to get busy **now** and take an agency for the Brush Runabout.

First convince yourself that the car is right. We have been manufacturing the Brush Runabout for over a year, and selling all we could make. Every month the car has been better than the month before. Now the new Model B, in which are collected all the features that have proved best, from which has been eliminated every feature that has proved troublesome in the hands of the unskilled user, the whole crystalized into an harmonious unit and clothed in an external design more pleasing to the eye than any small car in existence—this car is actually and literally not only the **best,** but the **only** car of its class. You, yourself, know how many buyers there are in this class.

Our records—such straws as the winning of the Algonquin Hill Climb, various endurance tests, the five car efficiency run just completed, the testimony of users, the adoption of our $600.00 Delivery Wagon by the Post Office Department at Washington—all speak for themselves. The genius of Mr. Brush, the ability and long experience of our manufacturing heads, the equipment and organization now tried out and molded into condition by the year and a half of work together on this one car means much to you.

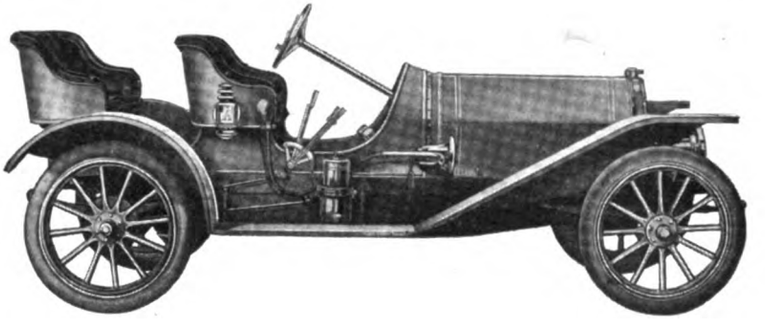
Your final investigation should be a visit to our factory. We will show you new cars, cars and parts in work, every process and material, cars that have run thousands of miles, and we will give you every facility for finding out everything, testing everything.

There have been remarkable sensations before now. There will likely be more of them. Two of the biggest concerns startled the trade, way back, with $500.00 announcements. What did they turn out to be? How many strings were there to them? What discounts and conditions applied? How long did it take them to develop? **HOW MUCH MONEY DID DEALERS MAKE OUT OF THEM THE FIRST YEAR FOLLOWING THE ANNOUNCEMENT?**

Meanwhile, here is the Brush Runabout, purified by the fire of a year and a half experience in manufacturing, delivery and use, still on deck in spite of dire prophesies, with none but friends among its dealers and users, actually delivering every day—now—a better car than expected, but at the same price and regular discounts.

Will it pay you to forget your daily bread to chase the will-o'-the-wisp of "swell propositions"—marvels of the typographical art—astounding promises of the to-be-but-not-yet?

We stake our corporate word and our individual word, every one of us (and you know who we are), that the Brush Runabout Model B is the "rightest" little car ever built. It runs right, stands up persistently, has lots of power, has the sweetest, cleanest control you ever saw, and what we have always said about its durability is so. The lines of the Model B are so graceful and its finish so neat that people fall in love with it at sight.



We have not taken and will not take on more dealers than we can supply. Come in now if you want to be sure of a sure thing. Don't wait—you have lots of time to figure on the will-'o-the-wisps, but the Brush Runabout is a **right-here-now** thing.

BRUSH RUNABOUT COMPANY, Detroit

1909

Overland

Model 34, 6-Cylinder

$2,000

SPECIFICATIONS:

6-cylinder, vertical motor, cast singly.
Bore, 3½; stroke, 4½.
H. P., 35.
Lubrication—mechanical oiler, positive driven.
3-point suspension.
Water cooled, Thermo-siphon.
Spark and throttle control on top of steering pillar.
Double system of ignition with high tension magneto.
Three-speed selective transmission on rear axle.
Shaft-drive, bevel gear.
Internal expanding and external contracting brakes on hubs.
Wheels, 34x3½", Artillery type.
Goodyear Q. D. rims.
Water capacity, 6 gallons.
Gasoline, 12 gallons.
Wheel base, 116 inches.
Tread, 56 inches.
Half elliptic front springs.
Full elliptic rear springs with involute ends.
"I" beam front axle.

Equipped with high-tension magneto, headlights and generator, oil side and tail lamps, horn, and full tool and repair outfit. All bodies ironed for tops.

A choice of four bodies is given on the Model 34 Chassis.

Roadster with single rumble seat.
Roadster with double bucket seat, as illustrated.
Toy tonneau of exceedingly attractive design, and
Five Passenger straight line tonneau.

THE OVERLAND IS NO EXPERIMENT. THE OVERLAND HAS MADE GOOD.
THE OVERLAND AGENTS HAVE MADE AND WILL MAKE MONEY.

Write for specifications on our 4-cylinder models.

To The Trade:

Owing to a misunderstanding caused thru information furnished it by one of our competitors, the Mechanical Board of the A. L. A. M. approved for adoption a certain type of Quick Detachable Rim.

This action was taken, however, before the said Board had inspected or even considered the compromise Rim offered by the Goodyear Tire & Rubber Company, and—furthermore—before it knew we were absolutely without representation before it in all its deliberations in connection with the selection of a Standard Rim—all due to the above misunderstanding.

We happened to come in contact with the Board in a most casual way, and after learning of its decision, had a general understanding, after which:

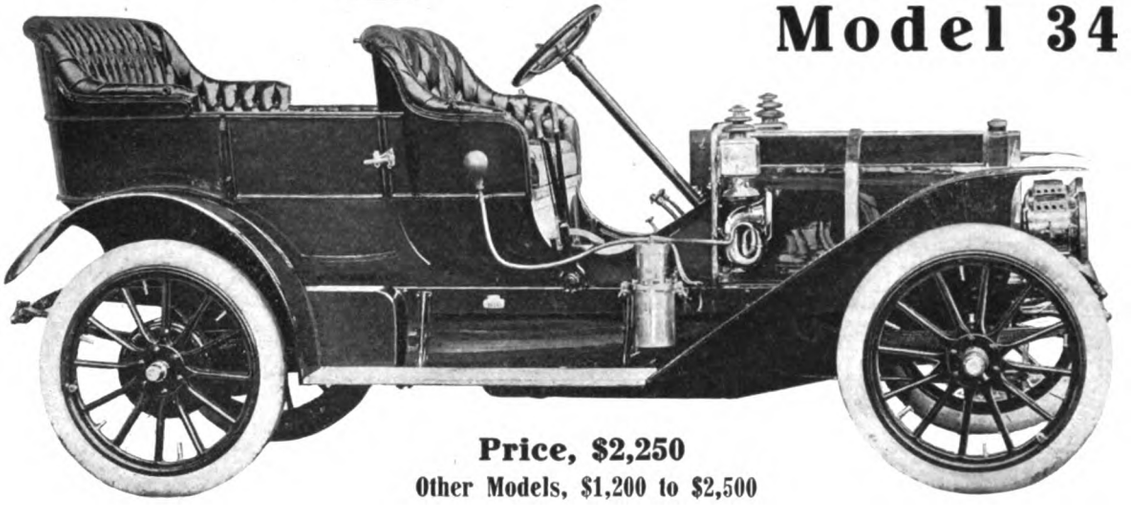
Digitized by Google

It decided to hold in abeyance the adoption of a Standard Rim until this Company had an opportunity to present its side of the case.

Therefore, truthfully speaking—

The A. L. A. M. Mechanical Board has not finally adopted a Standard Rim, and will not do so until the Goodyear Tire & Rubber Company has been given a square deal.

The new Goodyear Compromise Rim has reversible Side Rings; dispenses entirely with the use of an extra rubber filler; meets every requirement of all tire manufacturers as regards measurements; and is so superior to the Rim proposed for adoption that there is no question but that it will be the final choice of the A. L. A. M. Board—and, in fact, all manufacturers of automobiles.



The Goodyear Tire & Rubber Co.

Rambler

Model 34

Price, $2,250
Other Models, $1,200 to $2,500

TRY IT ON THE HILLS

Test this car at half speed on a hill or sand road where power and every ounce of it is needed. Notice how steadily and powerfully it pulls when running slowly under load.

The capacity of the offset crank shaft for doing this extra work is most noticeable at low engine speeds. All that power which in other engines is lost through friction on the bearings and cylinder walls, is added to the driving force by the Rambler offset crank shaft. It reduces friction; eliminates hammer on bearings; gives more power.

The straight line drive delivers the power direct and with least frictional loss to the rear axle. Let us demonstrate these features and the silence and the comfort of this car.

Tell our nearest representative to call at your home and take you to your place of business some morning in a Rambler. Or write your name and address and "Model 34" on a postal and mail to us today.

THE CAR OF STEADY SERVICE

Thomas B. Jeffery & Company, Main Office and Factory: **Kenosha, Wis.**

THE MOTOR WORLD

Volume XVIII. New York, U. S. A., Thursday, August 27, 1908. No. 22

SWEEPING REDUCTIONS ON TIRES

Diamond Rubber Co. First to Announce New Figures—Same Prices Apply on Clinchers and Quick Detachables.

The tire situation, which has come to mean the new prices which will prevail on tires, undoubtedly will unfold itself with great rapidity within the next ten days.

As has been plain for several months past, the tire manufacturers have not been slow to appreciate the evils that have grown out of the inflated and fictitious list prices and the correspondingly large discounts that have prevailed, to which the Motor World was first to direct attention. These conditions have served to permit the price-cutters, bargain counters and so-called "discount houses" to wax fat at the expense of the legitimate trade and the public and it was to correct these abuses that the tire makers have been bending their efforts. It was well known that reductions were in prospect, but as little could be learned of their exact extent, every one concerned has been awaiting with undisguised anxiety the announcement of the new figures.

The Diamond Rubber Co. was first to relieve this suspense. Their list prices for their 1909 tires were made public this week. They disclose sweeping reductions all along the line, both in respect to casings and tubes. The range of the reductions is shown on the prices which formerly applied and which hereafter will apply on the more popular sizes. For instance, the 28x3 Diamond casing which previously retailed for $22.65, is now listed at $14.05, the tube which sold for $5.05, now is catalogued at $3.50. The 30x3 has been reduced from $24.40 to $15.05; the 30x3½ from $31.55 to $22.20 and the 34x4 from $45.25 to 34.50. The list of the corresponding inner tubes have been lowered respectively from $5.40 to $3.75, from $7.45 to $5.05, and from $10.20 to $6.90.

Not the least significant feature of the Diamond Rubber Co.'s new scale is the fact that the same prices apply alike to both the clincher and quick-detachable types of wrapped tread tires. Heretofore, the quick detachable has been held at an advanced figure. The new scale in its entirety is as follows:

Size.	Casing.	Tube.
26 x 2½	$10.90	$2.80
28 x 2½	11.80	3.05
30 x 2½	12.70	3.20
32 x 2½	13.65	3.40
34 x 2½	14.55	3.55
36 x 2½	15.40	3.75
26 x 3	13.00	3.25
28 x 3	14.05	3.50
32 x 3	15.05	3.75
32 x 3	16.10	3.95
34 x 3	17.15	4.25
36 x 3	18.15	4.50
38 x 3	19.20	4.70
28 x 3¼	16.80	4.60
28 x 3½	20.65	4.70
30 x 3½	22.20	5.95
32 x 3½	23.55	5.35
34 x 3½	25.70	5.70
36 x 3½	27.80	6.00

White Steam Cabs Make Their Appearance.

Two White steam taximeter cabs have made their appearance—the first of the cab output of the White factory. They are of 20 horsepower and of the convential design of such vehicles, and are equipped with American taximeters.

RICE AND JOHNSON THE BIDDERS

Identity Disclosed of Prospective Purchasers of Pope-Waverly Plant—Their Offer Uncovers a Big Cash Balance.

September 7th is the date set by the Chancery Court of New Jersey for a hearing on the petition of the receivers of the Pope Motor Car Co., for instructions as to whether or not they shall accept the offer made for the Pope-Waverly plant in Indianapolis. The hearing will be held in Chancery Chambers, Newark, at 10 o'clock a. m.

The petition was presented to the court on Thursday last, and contrary to first reports, it disclosed that the bidders for the property are Herbert H. Rice and Wilbur C. Johnson, of Indianapolis, who are the same men who, soon after the Pope failure, formulated and printed a prospectus of the "Waverly Motor Car Co." with a view to acquiring the Pope-Waverly plant. Mr. Rice is, and has been, the manager of the factory, Mr. Johnson being associated with him in the management. The price they have offered for the plant and all rights to the business, except the cash in bank, is $200,000. The amount of this bank balance proves to be surprisingly large. On June 30th last it was $106,420.71.

As is well known, the capital stock of the Pope Motor Car Co. is owned or controlled by the Pope Mfg. Co.

Gramm Locates at Bowling Green.

The Gramm-Logan Motor Car Co. has completed its organization with J. B. Wilson, president; B. A. Gramm, vice-president and general manager; and Fred Bisantz, superintendent, and has located in Bowling Green, O., just south of Toledo. The product will be an improved type of truck, similar to the Logan truck which Gramm designed when with the Logan Construction Co., of Chillicothe, O Several other commercial models are in view.

The Week's Corporations.

Topeka, Kan.—Auto Carriage Co., under Kansas laws, with $15,000 capital.

Jacksonville, Fla.—Ideal Auto Manufacturing Co., under Florida laws. Corporators—Hugh Partridge, T. A. Stewart, and C. E. Clarke.

Miilwaukee, Wis.—Wisconsin Automobile Exchange, under Wisconsin laws. Corporators—L. Deetjen, A. F. Eckstein and Theodore Deetjen.

Chicago, Ill.—Straight-Roberts Auto Co., under Illinois laws, with $75,000 capital; automobile business. Corporators—J. R. Roberts, J. J. Straight and N. Goltra.

New York City, N. Y.—Gyroscope Automobile Co., The, increase of capital from $5,000 to $100,000. Attorneys—Palmer & Sereles, 68 William street, New York City, N. Y.

Pittsfield, Mass.—Motor Transportation Co., under Massachusetts laws, with $50.000 capital; to manufacture automobiles. Corporators—A. Sampson; R. Schaff, Newton, Mass.

Springfield, Ill.—Four Drive Auto Co., The, under Illinois laws, with $250,000 capital; to manufacture and sell automobiles. Corporators—C. T. Murphy, A. P. Dewey, L. E. Hill.

East St. Louis, Ill.—Mississippi Valley Automobile Corp., under Illinois laws, with $50,000 capital; general automobile business. Corporators—Henry S. Turner, Jr., John H. Phillips, William J. Peck.

Boston, Mass.—Taximotor Cab Company of Boston, under New Jersey laws, with $500,000 capital; to manufacture motor vehicles. Corporators—Cornelius A. Cole, Richard F. Tully and Franklin Vreeland.

Lowell, Mass—Lowell-American Automobile Co., The, under Massachusetts laws, with $100,000 capital; to deal in automobiles. Corporators—John F. Spaulding; Moses Lahue, Lowell, Mass.; Jesse G. Hanson.

New York City, N. Y.—Saratoga Auto Top and Body Co., under New York laws, with $15,000 capital. Corporators—Adolph J. Shary and Anna D. Shary, 336 West Seventieth street; Henry A. Blumenthal, 135 Broadway, New York City, N. Y.

Plattsburg, Pa.—Aldridge Roller Bearing Mfg. Co., under New York laws, with $200,000 capital; to manufacture vehicle bearings. Corporators—L. J. Aldridge, Plattsburg; M. F. Aldridge, Dr. A. W. Fairbanks, Chazy, Pa.; B. G. Hitchings, New York City, N. Y.

McCue Will Make Parts, Not Cars.

Despite the published reports to the contrary the McCue Co., Hartford, Conn., will not engage in the marketing of complete cars. The concern merely has added automobile parts and chassis to its older business of supplying carriage parts to the manufacturing trade. Its new line will include a complete line of forgings, brake and control levers, hubs, bearings, and axles, and it will be able to produce an assembled chassis, ready for body or with body in the white. No finished cars will be delivered, however, and the predicted "McCue-Hartford" will not appear.

"Desert Flyer" Will Leave Nevada.

After they have succeeded in selling about 10,000 shares of stock to citizens of Council Bluffs, Ia., the promoters of the Independent Transportation Co., which has been organized there, will have the Nevada Motor Car Co., with which it is interrelated, make a number of big passenger and freight cars for service between Council Bluffs and Omaha. The Nevada company is to move from Reno to Council Bluffs and establish its factory, arrangements for leasing a factory at Washington avenue and North Main street being under way. So far the chief product of the Nevada concern, which has been capitalized at $500,000, has been one "Desert Flyer," an immense car weighing five tons, capable of running on prairie, desert, street or railroad tracks.

Kokomo to Celebrate an Anniversary.

Kokomo, Ind., made famous by the Haynes and Apperson automobiles, and more recently by Will Hodge in Booth Tarkington's play, "The Man from Home," will celebrate the fifteenth anniversary of the motor car industry there. An invitation will be extended to all Indiana motorists to participate in the festivities, George Ade included. Automobile races, a parade, gymkhana and other entertainment will be given to make the day, September 2, a great one.

New Haven Invites Bids for a Runabout.

Bids for an automobile runabout are being solicited by the board of fire commissioners in New Haven, Conn. Sealed proposals for a machine to meet the board's specifications, which are on file, will be received up to September 2. Forms and information may be obtained from S. J. Metzger, secretary of the board.

Rutz Joins New Departure Staff.

W. F. Rutz, formerly roving representative of the Continental Caoutchouc Co., has joined the staff of the New Departure Mfg. Co., Bristol, Conn. He will be identified with the recently instituted ball bearing department of the company.

Arbuckle Becomes Winton Supervisor.

Sales Manager Churchill, of the Winton Motor Carriage Co., has appointed George Arbuckle chief of Winton supervisors. Arbuckle has been on the Winton staff since 1902 and is well known to the trade from coast to coast.

Baker to Sell Perfection Springs.

E. F. Baker, of Boston, has joined the forces of the Perfection Spring Co., of Cleveland. He will have charge of the territory east of Buffalo.

In the Retail World.

The Gyroscope Automobile Co., of New York, has certified to a large increase of capital—from $5,000 to $100,000.

The Michigan Automobile Co. has opened a garage on Sixth street, Red Jacket, Mich. It will be in charge of Paul Pawler.

The Wilson Automobile Co., of Wichita, Kan., has been sold to J. H. Butts & Son. The business will be continued at 118-120 South Lawrence avenue, its present location.

The Hoff Automobile Co. has been organized in Tucson, Ariz., and has taken a location at Broadway and Scott streets. The concern will do a renting, repair and agency business.

The Irvin Automobile Co. has started business in Jefferson, Ia., headed by Edward Irvin. In addition to handling the Mitchell, the concern will do a general garage business.

The Glens Falls Automobile Co., of Glens Falls, N. Y., has moved into its new three story brick and concrete garage at the top of Glen street hill on Trunk Line road. The building has storage capacity for 100 cars, and is equipped with repair department, paint shop and all modern improvements.

The small amount of $21.35 is involved in an appealed case which is to be tried before the Circuit Court at Portland, Ind., but the question at issue is somewhat important. Arthur V. Jones, of the Jones Cycle and Automobile Co., Portland, won in a suit tried before Squire A. G. Lewis, a local magistrate, wherein the Bird-Sykes Co., of Chicago, sought to recover $21.35 for repairs on an automobile. Jones resisted the claim on the ground that the plaintiff company had sold the automobile to him, and that the repairs were to be furnished by the sellers.

Where Imitation is Made Expensive.

That trading in imitations has its dangers from a legal standpoint has been again emphasized by the action of an English court in imposing a fine and costs amounting to over $250 on a London and Paris firm for selling imitation De Dion automobile parts as the genuine. It was proved that the defendants had supplied customers with valves, represented as of De Dion manufacture, that were De Dion only in form and appearance, and the court was prompt in punishing the false trade description.

Wants to Get Rid of Apprentice.

One of the first apprenticeship cases in years to get into court has developed through the action of the Cadillac Motor Car Co., of Detroit, Mich., in seeking to be relieved of its parts of a contract with John Bunge concerning his son, Ernest T. Bunge. The company claims the boy did not keep his part of the contract, and therefore asks that the agreement be declared void.

UNUSUAL SUIT OVER DISCOUNT

Maker and Agent Lock Horns Over Parts Used in Repairing Car at Factory—Verdict for Agent.

Judge Hodson, in the municipal court at Buffalo, N. Y., has decided in favor of the defendants, the Centaur Motor Co., a suit brought by the Winton Motor Carriage Co. of Cleveland, Ohio, which involved an unusual and interesting point.

It appears that in 1907, when the Centaur company was the Buffalo agent for the Winton cars, an automobile was sent to the factory for repairs. In the course of the repairing, new parts to the value of $211.98 were incorporated. When the car was returned to Buffalo, the bill rendered included the full value of these parts. The Centaur people refused to pay it, claiming that under the terms of their agency agreement they were entitled to 25 per cent. on all parts. The Winton company declined to allow the discount and the suit resulted.

In his opinion Judge Hodson says:

"It seems to me that the contention of the defendant is reasonable. It is admitted that he would be entitled to the discount if the parts put on had been sent to Buffalo unattached. I am unable to see why it interferes with the defendant's rights that the parts were sent attached to the automobile. No matter how they got here, they were delivered to the defendant's order and he should have the commission."

British Imports and Exports Shrinking.

British imports of automobiles, chassis and parts have shown a steady increase for the first six of the seven months from the first of the year the total for the seven months ending with July amounting to £2,598,076. Although marked with monthly increases this total is not quite so large as that of last year for the same period, which was £2,934,688. During the seven months period of 1908, the gross imports of complete cars were 2,724 machines, having a value of £986,571, while incomplete chassis to the number of 1,882 were imported, with a value of £608,679. By far the largest item, however, was the importation of parts which for the period reached £1,002,826. The returns for the month of July show a decrease of £34,808 as against the importation of cars, chassis and parts during July, 1907, making the trend of the month at variance with those which preceded it this year. Of complete cars 421 were imported during the month, having a value of £145,142. The number of chassis imported was 306, valued at £99,076, while the importation of parts aggregated £166,760, making a combined total of £410,978 as against £445,786 in the corresponding month last year.

Falling off in the British exports is indicated both in the returns for July and for the seven month period. While the total in July, 1907, was £108,836 the figure for July of this year is but £83,993. The latter total was made up of the exportation of 137 complete cars, having a value of £54,665; and 5 chassis, valued at £1,725, together with parts to the amount of £40,730. The gross shipments during the seven months ending with July are returned at £677,139, which contrasts with £692,542 in the similar period last year.

Two New Travelers for Winton.

The Winton Motor Carriage Co. has engaged George H. Smith and Charles S. Calvert to cover eastern and western territory respectively. Smith was formerly Philadelphia branch manager for the White Co. Calvert has for several years sold Wintons in Newark, N. J., as a member of the firm of Calvert & Zusi. He has, however, disposed of his interest in the business.

Motor Stages for Michigan Promoters.

"From Hancock to Houghton" is the battle cry of Michigan promoters who are organizing a $50,000 company to operate a line of automobiles between the two cities across the Portage lake bridge. The cars to be used are 20 passenger machines, such as have proved highly profitable between Red Jacket and Laurium, Mich., and on other Michigan lines.

Kissel Doubles Capital and Will Enlarge.

The Kissel Motor Car Co., Hartford, Wis., has increased its capitalization from $100,000 to $200,000. Much of the added money will be used in the construction of a four story, 50 by 130 feet, addition to the plant, which when conpleted about Nov. 15 will enable the company to produce its own tops, fenders, hoods and other parts.

Revolutionizer Coming from Georgia.

With a capitalization of $100,000, the Atlanta Motor Co., of Atlanta, Ga., will shortly commence to "revolutionize automobile manufacture" with a device invented by William Knox Cleveland for applying power to all four wheels. Associated with Cleveland are Herbert L. Wiggs, Eugene Callaway and V. L. Smith.

Aurora Formally Declared a Bankrupt.

The Aurora Motor Works, Aurora, Ill., having been formally adjudicated an involuntary bankrupt, Thomas S. Huntley, as referee in bankruptcy, has set September 7 as the date for the first meeting of its creditors. It will be held in the court house at Geneva, Ill.

To Make Runabouts in Waldron.

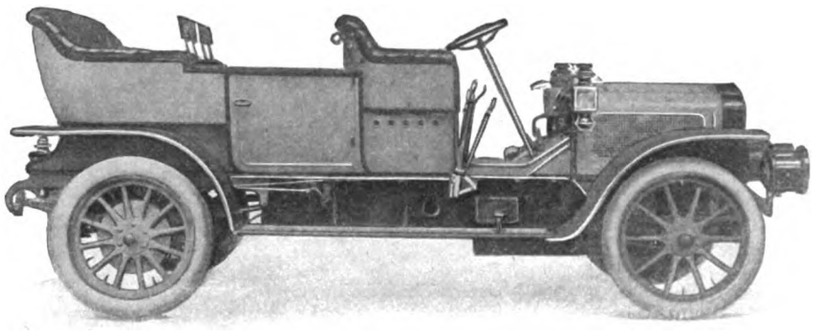
A runabout at $500 is promised as a Waldron, Ill., product, the Waldron Runabout Mfg. Co. having recently been organized in the little village. Work has already been commenced on the new factory which the concern will occupy.

BIG BRITISH MAKER GOES UNDER

Gilt Domes and Marble Halls Fail to Save Argyll, Ltd.—Liabilities Total More Than $4,600,000.

One of the first of Great Britain's moderate price car manufacturing concerns, Argyll Motors, Ltd., is in hot water, threatened with bankruptcy and dissolution. Payment on its June debentures had to be passed and an "extraordinary general meeting" of the shareholders was called. The company had a remarkable rise from the ashes of a derelict cycle parts manufacturing concern known as the Scottish Manufacturing Co., of Bridgeton, Glasgow. Its early cars were assembled around standard motors and sold at so modest a price as to create an enormous demand.

This demand was made the basis of a $2,500,000 capitalization and stock flotation. The biggest exclusively motor car works in Europe was built on the shores of Loch Lomond, at Alexandria, near Dumbarton, which besides a general de luxe effect throughout, had gilded domes and marble halls that quite astounded the thrifty and cautious Scotch business men of the locality. In addition to the money from the stock more was found necessary, and a bond issue of $850,000 was put through. Having been unable to meet the interest payments on this and with its affairs in desperate shape, the stockholders were called together by the directors.



At the meeting the shareholders were told that they would have to agree to the company's voluntary liquidation or the creditors would throw it into compulsory bankruptcy. Voluntary liquidation was therefore agreed upon, with grumbling at the haste of the proceedings. The liabilities amount to $4,664,050 and the assets to $3.808,790. An effort at reconstruction is being made.

Too Much Grand Prix Ruined Weigel.

Having in a measure staked its business future on the probability of its cars making a good showing in or winning the Grand Prix race, Weigel Motors, Ltd., an English concern which has gained both fame and notoriety through the exploits of its chief, has gone into the hands of a receiver. Holders of the first debenture bonds objected to the fact that they did not get their interest payments. Over $15,000 was spent by the firm in competing in the Grand Prix, at a time when the company was badly in need of ready money. Weigel himself is credited with having said before the race, "If I win or go near I shall expect two or three years' good trade on my lines. If I do not, I lose a couple of thousand pounds." The poor showing of the cars and the accidents that befell them increased the loss, and brought about the receivership.

THE 1909 WHITE STEAM CARS

During the coming season, the White Steam Cars will be built in two distinct models which, while differing widely in size, in power and in price, will follow the same general lines of construction. The horse-power ratings of these cars are based on the actual power delivered at the rear wheels, not merely on formulas or on the power delivered at the engine.

The larger of the new cars (shown in the above illustration) is known as the Model "M." It is rated at 40 steam horse-power and sells for $4,000, f. o. b. Cleveland, equipped with acetylene headlights and tank, oil lamps, horn and tool kit. The wheel base is 122 inches; the front tires 36 x 4 inches and the rear tires 36 x 5 inches. The car is regulary equipped with a straight-line seven-passenger body.

The smaller of the cars will be known as the Model "O." It is rated at 20 steam horse-power and sells for $2,000, f. o. b. Cleveland, equipped with oil lamps, horn and tool kit. The wheel-base is 104 inches and the tires, both front and rear, are 32 x 3½ inches. The car is regularly equipped with a straight-line five-passenger body.

The power plants of the two models are identical in design, the only difference between them being in the dimensions of the various parts. The principal mechanical change in the new cars, as compared with previous White models, is in the engine. The new engine is fitted with the Joy valve mechanism, instead of the Stephenson valve mechanism. The valves are driven from the connecting rods, as are the pumps. The eccentrics are done away with and the cylinders are brought close together, permitting the use of a short one-piece crank-shaft, with but two main bearings. The number of parts in the engine is reduced by one half and the entire construction greatly simplified.

As in previous models, the generator — the simplest steam-making device ever designed — consists simply of a series of coils of steel tubing joined together. The regulating system, whereby the temperature and pressure of the steam remain constant without in any way engaging or requiring the attention of the operator, is similar to that in the 1908 cars.

A Circular containing full details of the New Models will be sent on request.

Impressive Recovery of the Industry.

When the dubious outlook following the panic of last fall is considered it appears not alone that many of the storm signals were heeded in season to avert disaster, but that despite the unpropitious outlook an impressive volume of business has been done during the first half of the present year. A clue to the volume of sales made by the American makers during this period is furnished by the report of the receivers of the Electric Vehicle Company in which the income from the Selden royalty, which is figured on a 1 per cent. basis on all cars actually sold, is set down as $236,915.77. Working on this basis, and making practically no allowance for the sales of October, November and December, when the series of shows and the panic combined to stifle almost entirely the usual business of that season, it is fair to allow a gross income from sales of approximately $24,000,000 to the makers who are numbered with the Association of Licensed Automobile Manufacturers.

A careful canvass of the remainder of the industry shows a probable output of 77 other manufacturers amounting to no less than $23,190,000. This total includes a conservative estimate of the gross business done by the established makers of gasolene, steam and electric cars, and ignores a number whose income is more or less doubtful. In addition, it is unquestionable that at least $2,000,000 worth of business has been done by importers in the sale of foreign built pleasure cars and taximeter cabs, during the period referred to—January to July, inclusive.

On this basis, it is possible to conservatively place the gross sales of the entire industry at $50,000,000, which probably is an under-estimate. In addition to this sum, a large volume of sales of second-hand cars to new purchasers also has been consummated, but it is not possible even to guess at the value of that department of the industry. The movements of the second hand market, while practically an unknown quantity in the aggregate, constitute a tremendous factor in the annual turnover of money in the industry. In the export field, though no gain has been shown as compared with the corresponding period of a year ago, the total volume of business during the first six months of the current year, has been upwards of $2,970,000, of which $2,634,606 was the valuation of cars exported alone.

It is questionable whether any other industry producing a finished article can boast as creditable a showing. In place of the general downfall which at one time appeared to threaten, enough business has been done to more than fulfill the expectations of the most optimistic, the majority of manufacturers have been able to clean up their outputs without difficulty, and in place of the patching up process which might have been anticipated at this time, they find themselves enabled to go ahead with their plans for the coming year with clean assembling floors and wholesome balance sheets.

Latitude of One-Design Plan.

Not alone mechanical and constructional advantages attach to the policy which seems to be growing in favor with manufacturers, of making whatever variety of chassis their line affords one simply of size rather than design. There exist commercial or selling advantages, as well, which the men who are in the field are in a position to appreciate.

A preponderating proportion of makers long since have abandoned the idea of attempting to supply from one factory every type and size of car that the immense public may have a mind for, and while permitting a wide range of choice as to body and fittings, have latterly inclined toward a reduction of chassis styles and a concentration on a few models or even one. In some notable instances where more than one chassis is supplied, each type is distinguished from the others chiefly in the scale of its dimensions, the features of design being uniform in all. Thus the smallest chassis is but a reduction of the larger ones and whatever points of excellence are to be found in one are to be found in all.

Production is simplified in such a case by what the models have in common in the choice of metals, methods of testing and the assembly. There is not the diversity of single, double, four and six cylinder engines, shaft and chain drives, sliding gear and planetary transmissions, and the multiplication of problems that are born of trying to make one factory force master the manufacturing difficulties of several radically different types and handle them all in a smooth and steady flow.

But as production must of necessity take direction from sales needs and policy, there must be justification in the latter, also, before a final commitment to the one design plan. Unlike a wholesale merchant, a manufacturer's success and patronage is not dependent upon his ability to supply extremes and variety of market demand, but upon particular and specialized merits of his product. Especially in the automobile field is emphasis laid upon alleged points of superiority residing in certain exclusive or unusual features of design, and if the claims made bear the color of truth and are susceptible of convincing argument they are worthy of the whole line and not for a confinement to but one of the manufacturer's several types.

Having brought the prospective customer to a knowledge of the excellences of a car's material and design, it is then but a matter of helping select the size and power best suited to his requirements, a selection which presents no conflicts of the respective advantages of this or that radically differing feature. The uniformiy of the design through the several sizes permits of a concentrated and cumulative persuasion of the public as to characteristics or superiority,

Digitized by Google

under which all of the sizes should benefit.

Where a maker casts an anchor to windward by developing a field for his products outside the pleasure and touring car domain, such as taximeter cabs, town cars, and commercial coaches and wagons, imperative reasons may frequently present themselves for special designs to meet the peculiarities of the service. In such a situation the questions to be met are those of a separate and distinct business.

Variation in body mounting in itself makes a concession to the individual demands of customers that covers a wide range, and before the possible combinations of different bodies with several sizes of chassis have been exhausted, the manufacturer has sounded a lengthy scale. This lessens the necessity for introducing the confusion incident to the presentation of markedly dissimilar chassis designs, and conserves the identity and reputation of the product. The one design plan thus allows great latitude in the markets sought while being a useful extension of the one car production ideal.

For the Rescue of "Fair Fame."

"Dunc" Curry "took a rise" out of the Motor World one day last week. "Dunc" doesn't like the American Automobile Association, or rather some of the officials connected with it, and it has pained him greatly that the Motor World should say anything in its favor and at the same time point out the influences at work in New York to bolster the shallow pretentions of the Automobile Club of America to appear as the dominating factor in American affairs.

Apparently Duncan—the "boys" all call him "Dunc"—was somewhat roiled by publication of the fact that the club has presented many of the "boys" with membership cards entitling them to the privileges of its cafe, library, etc; though far be it from the Motor World to suspect that Curry himself would accept the bit of pasteboard. For, though the residents of Keokuk possibly may not be aware of the fact, Mr. Curry is one of Mr. Hearst's scouts, and Mr. Hearst scarcely would stand for that sort of thing, least of all when a more or less capitalistic club is concerned. "Dunc" however, usually is so well disguised as an "auto editor," that not all of "the bunch" have yet penetrated his disguise, although he wears no whiskers to deceive them. Being "close to the boss" and having his ear at all times, Editor Currie writes only when he feels like it, which is not as often as may be imagined. But when he does write and "take a rise" out of any one, the "other fellow" is supposed to curl up and remain mum forevermore.

In the course of his withering blast last week, "Dunc" performed a large job of mind reading. He declared that the editor of the Motor World and every one else knows that "the A. A. A. is rotten from top to bottom, and that its conduct of tours and racing is a standing disgrace to the fair fame of the sport and the industry." It is a pity to injure Duncan's fair fame as a clairvoyant, but unfortunately we not only know nothing of the sort, but we take no stock in such idle and sweeping assertions. The rottenest thing with which we are familiar are the methods employed to make the A. A. A. appear in that light, nine-tenths of which spring from the personal dislikes and personal grievances of men with axes to grind.

Of course, we are aware fully that the American Automobile Association is not perfect or above criticism. No organization that necessarily must deal with aggrieved or otherwise disgruntled race promoters and competitors and hard losers generally ever will be able to satisfy every one. But we several times have pointed out how the A. A. A. can become near-perfect. We have publicly and specifically nominated several of the "boys" for the various offices within the gift of the association. We even nominated one of them for all the offices and the manner in which our suggestions were utterly ignored by the A. A. A. entitles us to be sorer even than Mr. Curry. It is true we overlooked Tom Moore, and, also, failed to nominate Mr. Curry himself, but it was an oversight for which we apologize. For we know only too well that Fair Fame is longing to be rescued by their protecting arms.

Meanwhile the A. A. A. remains the governing body in America and, as the Motor World stated last week when it aroused Mr. Curry so unduly, only A. A. A. sanctions are recognized, and should be sought. Anyone who does otherwise merely is being bluffed and led astray by men with grievances who are misusing their newspaper connections in trying to "get even." None is better acquainted with this exceeding large truth than Mr. Duncan Curry.

COMING EVENTS

Sept. 1, 2, 3, and 4, Chicago, Ill.—Chicago Motor Club's postponed 1,000-mile reliability run.

September 5-9, Los Angeles, Cal.—Automobile Dealers Association's reliability run to San Francisco.

Sept. 7, Columbus, Ohio.—Columbus Automobile Club's race meet.

September 7, Lowell, Mass.—Lowell Automobile Club's 200 miles road race, on Merrimac Valley boulevard.

September 7, Columbus, Ohio.—Columbus Automobile Club's race meet.

September 7-12, Hartford, Conn.—Connecticut State Fair Association's outdoor show and grand circuit races at Charter Oak Park.

September 11, Springfield, Mass.—Springfield Automobile Club's hill climb on Wilbraham hill.

September 12, Louisville, Ky.—Louisville Automobile Club's race meet at Churchill Downs.

September 14, Chicago, Ill.—Chicago Motor Club's annual economy run.

September 20, San Francisco, Cal.—Olympic Athletic Club's race meet at Tanforan Park.

September 23-24, Boston, Mass.—Bay State Automobile Association's 24 hours endurance run, Boston to Bretton Woods, N. H.

October 6-9, Chicago, Ill.—Chicago Motor Club's 1,000 miles reliability run.

October 7, Philadelphia, Pa.—Quaker City Motor Club's 200 miles road race, Fairmount Park.

October 10, Long Island—Elimination trials for Vanderbilt cup contest.

October 24, Long Island.—Vanderbilt cup contest.

November 26, Savannah, Ga.—Automobile Club of America's (New York), 400 miles outlaw race for foreign cars.

December 31-January 7, New York City—American Motor Car Manufacturers' Association's annual show in Grand Central Palace.

January 16-23, New York City—Association of Licensed Automobile Manufacturers' annual show in Madison Square Garden.

January 23-30, Philadelphia, Pa.—Philadelphia Automobile Trade Association's annual show.

February 6-13, Chicago, Ill.—National Association of Automobile Manufacturers' show, Coliseum.

February 27-March 6, Hartford, Conn.—Automobile Dealers Association's annual show.

THOMAS TURNS FROM OUTLAWS

Refuses to be Used as a Catspaw and Withdraws His Cars—Makes Known His Reasons.

E. R. Thomas, the Buffalo manufacturer who had the wool pulled over his eyes by New York's lovely and limited "Racing Trust" during the excitement incident to the return of the New York-Paris winner, has discovered the real truth of the situation and does not mean to be made an "outlaw" for the benefit of a crafty promoter who is working for his own pocket, nor to be used as a catspaw for a couple of importers who have little, if anything, to lose. The Motor Racing Association, which apparently was organized by, and chiefly for the benefit of T. Francis Moore and Company, talked Mr. Thomas into entering a car in the coming 24 hours race at Brighton Beach, and Mr. Thomas surprised them more or less by promising to enter the self-same car that carried the flag around the world. Then when Mr. Thomas began to reflect that this Brighton affair is to be an outlaw meet, he soon changed his mind and announced that he would stand by the Three A's, enter a car in the Vanderbilt cup and let the Motor Racing Trust go to grass. If a Thomas car does perform at Brighton track on September 11 and 12, it will not be entered by the Thomas factory, nor authorized by Mr. Thomas. This manufacturer, a member of the A. A. A. racing board, who has done as much as any man in America, financially and otherwise, to promote racing and help America establish a name among the nations in international contests, is not a man to be deluded into any new fangled three-ring racing circus which is stirring up strife and creating trouble. Here is what Mr. Thomas said on Wednesday:

"All the Thomas cars entered in the 24 hours race to be held at Brighton Beach September 17 have been withdrawn for the reason that the E. R. Thomas Motor Co. cannot permit any of its cars over which it has the slightest control to participate in a race which has not received the sanction of the American Automobile Association, as it would disqualify our cars and drivers from all events outside of the metropolitan district.

"We believe that racing must be controlled by an authoritative body, and as the A. A. A. has been controlling racing for some years we see no reason why the conditions should change. In assuming this position I feel as if we voice the sentiment of the majority of manufacturers, without whose assistance races cannot be successfully run.

"Under instructions, H. S. Houpt has withdrawn his entries in the Brighton Beach race."

It is said that Mr. Houpt, who appears to be under the Moore "spell," will now enter a car on his own account.

Texas Lad Wins Long Race.

On Sunday, August 23, at San Antonio, Texas, A. Dehymel, a 17-year-old boy, driving a 40 horsepower Stoddard-Dayton roadster, won the 12 hours race on the three-quarters of a mile track, covering 429 miles. It was the first time that young Dehymel, who is an amateur, had ever driven in a track race and he beat a number of seasoned men, including Harry Van Tine, who gained second place with one of the Glidden tour Studebakers stripped for racing. Van Tine finished 14 laps behind the winner. George Robbins's Mitchell was the only other survivor in the field of half a dozen contestants.

Tire trouble was plentiful throughout the race, caused by the poor condition of the track, Van Tine and the winner burning up nearly a thousand dollars' worth of tires. There was considerable skidding on the continuous turns of the small track, which provided occasional thrills for the spectators, but no accidents occurred. The non-survivors dropped out at various stages of the game, making the race rather tame, until the last hour or two when Van Tine made a desperate effort to catch Dehymel.

Holding Court by Correspondence.

Correspondence school methods of administering automobile "justice" have developed in Pennsylvania. Charles Davis, of Wilkes-Barre, the manager of a local garage, received a letter from a justice of the peace in Ambler, Pa., declaring that the motorist had the day before exceeded the speed limit of the town and should therefore appear in court at a stated time. The recipient of the letter replied by sending $5 and saying that he was sorry that he could not appear at the time specified but hoped that the amount enclosed would be satisfactory. In response to this, he got from the justice a communication reading: "Your letter received to-day, including the sum of $5 in part payment of automobile speeding. The fine and costs are $12.50, so you will please send the balance by return mail and avoid a trip to Ambler." The next mail carried a check from Davis to the Ambler justice for $7.50 more.

Hartford Club Chooses Avon Mountain.

After some careful searching and argument, Avon Mountain, North Corners, Conn., has been selected by the Hartford Automobile Club as the most desirable place to hold its hill climb on October 17. A committee composed of H. P. Maxim, C. H. Gillette and W. C. Russell made an attack on this hill in automobiles a few days ago and came to the conclusion that it was "most promising." The mountain course set around with the wildest, most rugged scenery will make the hill climb picturesque indeed, while the chances for spectacular driving on the sharp turns are many.

INSTRUCTIVE TRIALS PLANNED

New York Dealers Program Dust, Smoke and Brake Contests—Horse-Drawn Vehicles to Play Comparative Parts.

Popular and instructive as dust and exhaust trials have been abroad for some time, the first of these to be held on this side of the Atlantic will take place in September, at which time various makes of American cars will have the opportunity of showing their desirable qualities in such refinements as freedom from offensive exhaust and smoke and the ability to move at speed without raising undue quantities of the road surface and scattering it over the scenery. Brake tests will also be held in connection with the trials, and, if possible, comparative demonstrations of stopping in rivalry with horsedrawn vehicles of different kinds.

Central Park, New York City, has been selected as the probable theater of procedure and the tentative dates chosen are September 23 and 24, the New York Automobile Trade Association being back of the project. For the dust trials a 200 yards course will be covered with fine crushed lime stone and dried leaves, and the cars will proceed over it at a pace set by a flag attached to an endless belt arrangement the length of the course, which will be operated in accordance with the readings of a speeding indicator fastened to its controlling mechanism. The judges will be influenced in their decisions not only by their visual observations, but by instantaneous photographs that will be taken of the cars as they whirl along. Not only the effects of the body and running gear construction in dust raising will be considered, but also the effects of different types of tires, the results with hard tires, partially deflated tires and the several styles of studded treads being noted.

After the dust trials, the course will be well wet down, and the exhaust trials held. As in the case of the dust tests, photographs will be taken. It is proposed in the braking tests to have not only automobiles but trotting horses hitched to light sulkies, light road wagons and business vehicles, and the superioriy of the motor cars in making abrupt stops when necessary will only be demonstrated by excelling the performances of the horses in the hands of skilful drivers. Both the police and the park departments of New York City have sanctioned the trials, and will lend all possible assistance to their success, as the data that will be obtained will have great value to them in their dealings with automobiles in general.

The exhaust trials, particularly are looked forward to by the police department as likely to show results which will justify the exclusion of smoking machines from the parks. Many owners have claimed that smoke is a necessary accompaniment of motoring.

CONDITIONS FOR LIGHT CAR RACE

A. C. A. Outlines Its "Invitation" for American Support of Its Anti-American Program—Entry Fee $200.

After a meeting of the contest committee of the Automobile Club of America on Monday last, the firm of Mills & Moore announced the adoption of the rules and conditions for the light car race which as a sop for American manufacturers, the club added to its European program, which will be carried out at Savannah, Ga., in November next.

The minimum weight will be 950 pounds and the maximum bore on a basis of four cylinders has been placed at 3¾ inches. According to Mills & Moore, there was some discussion as to whether the bore should not be placed at 4 inches for a four cylinder car. It was found, however, that a 4-inch four cylinder bore would be too big in proportion for the average single cylinder and double opposed motor of to-day.

The length of the race has been placed at 200 miles, over a ten mile parallelogram which will be increased should there be more than 20 entrants.

The race will be run on Wednesday, November 25th, the day preceding the European event. According to the press agents, "this will insure an enormous crowd of spectators which would be impossible at any other date or place," but no diagram of explanation accompanied the statement.

The equivalent of bore for varying numbers of cylinders is as follows:

For four-cycle motors:

Of 8 cylinders	2.65 inches of bore
Of 6 cylinders	3.56 inches of bore
Of 4 cylinders	3.75 inches of bore
Of 3 cylinders	4.33 inches of bore
Of 2 cylinders	5.80 inches of bore
Of 1 cylinder	7.50 inches of bore

A provision has also been made for two-cycle motors, the bore on a basis of four cylinders being 3.18 inches, and for three cylinders 3.65 inches.

The entry fee for the race has been fixed at $200 for one car, $300 for two, $350 for three, and $400 for four cars.

"Rules" for Cross-Continent Contest.

Although it has already been frowned upon by the National Association of Automobile Manufacturers and by the American Automobile Association, the proposed stock car endurance contest from New York to San Francisco and back is still being cheerfully boomed by the New York newspaper which is championing the idea. Even a schedule and a set of rules have been formulated and published, providing for the start from New York on July 4th next, on a 49 days trip, the outward journey to be through Rochester, Cleveland, Detroit, Chicago, Omaha, Cheyenne, Ogden and Reno, to San Francisco, and after a 24 hours stay in the latter city, the return to be through Los Angeles, Goldfield, Ely, Salt Lake City, Denver, Kansas City, St. Louis, Cincinnati and Pittsburg to New York.

The rules have elaborate provision for the carrying of reporters, mechanics, spare parts and baggage, and stringent regulations as to repairs, replacements and running time, the whole mixture being flavored with generous sprinklings of phrases such as "if conditions permit," "if possible," "as frequently as practicable," and "in the good judgment of the contest committee." The contest was originally announced as a race, but the path of wrecked speed laws, smashed vehicles, and dead and wounded cattle, people and chickens that a speed race would leave in its wake presented a prospect that resulted in a radical modification to "endurance" contest.

Victorious Thomas En Route to Buffalo.

Buffalo has made elaborate preparations for the reception to the victorious New York-Paris Thomas car, which will arrive in that city next Saturday.

Before leaving for Buffalo, the car carrying Schuster, Miller, Montague Roberts and George McAdam, accompanied by some of the Thomas representatives, made a trip to Oyster Bay last Thursday, where the party was warmly received and congratulated by President Roosevelt at his residence. When the drivers were presented to the President, there was considerable mutual delight and when the Strenuous One saw the flag that had been carried around the world, he was proud of the boys. Mr. Roosevelt listened with great interest to Schuster's stories and anecdotes concerning the wild beasts encountered on the trip through Siberia, and seemed amused when the driver told him that the worst roads on the trip were found right in America.

Following this reception the car returned to New York, where an illustrated lecture on the great race was delivered by Orrel A. Parker at the Automobile Club of America. On Monday, August 24, the car set out for Buffalo, its native city, making stops at Poughkeepsie, Albany, Utica, Syracuse, and Rochester.

To Welcome the Olympian Athletes.

New York motorists, both private owners and those connected with the trade, are going to see to it that the reception to the victorious American Olympian athletes on Saturday next does not lack a glorious and spectacular aspect so far as the automobile is concerned. Nowadays no celebration is complete without a procession of motor cars to carry the honored ones and when the formal joyesse is tendered to the conquering heroes on Saturday, August 29, W. I. Fickling, chairman of the automobile division, will see that things are done with some class. He has made a general call for owners and dealers to donate the services of at least 75 cars to carry the athletes and committees.

KANSAS CITY HAS NO GRIEVANCE

Will Continue Affiliation with A. A. A., Despite "Colored" Reports—Has Withdrawn Only from the State Body.

Although the anti-A. A. A. press agents in New York have been indusriously sending broadcast reports that the resignation of the Kansas City Automobile Club from the Missouri State Automobile Association was proof of far reaching dissatisfaction with the American Automobile Association, the arrival of the truth from the West once more places the little band of eastern malcontents in an unenviable light. It appears that purely local reasons were involved; for though the Kansas City club is resigning from the State association, it states specifically that it will continue independent affiliation with the parent body. Its endurance contest next month also will be run under the sanction of the A. A. A. For some reason the treasurer and "chief worker" of the Missouri State Association, R. F. Britton, of St. Louis, has filed a protest against the Kansas City club's action. although in the same breath he claims that he is tired of his job and will hereafter work only for the St. Louis club.

Favors Foreign Routes for Glidden Tours.

Charles J. Glidden is credited with having radical ideas regarding the routes for future contests for the Glidden trophy.

"I believe that the tour of 1909 will be west of Chicago to Denver, and that in 1910 the trip will be made through England, with a possible tour of Europe in 1911," Mr. Glidden is quoted as saying. "The European trips will open the European markets to American cars and will do a lot of good.

"The western trip of next year goes through a territory which will provide great opportunity for development. The European trips to follow will give us an opportunity to show Europe what the American car really is, and altogether we have before us some interesting trips. The tour of this year provided opportunities for American cars and these opportunities were accepted, but the foreigners declined."

The Eagle on the Soup Tureen.

The disgruntled Automobile Club of America finally has accepted the design for the grand prize for the European road race which that New York club will conduct at Savannah, Ga., in November next. The design is by Tiffany and the artist was unusually apt in depicting the spirit of the occasion. The trophy takes the form of a rather deep soup tureen, on the rim of which is perched a disgusted-appearing American eagle, whose talons are entangled in a sprig of laurel and who holds in his beak a small laurel wreath which apparently he is making ready to drop into the soup tureen.

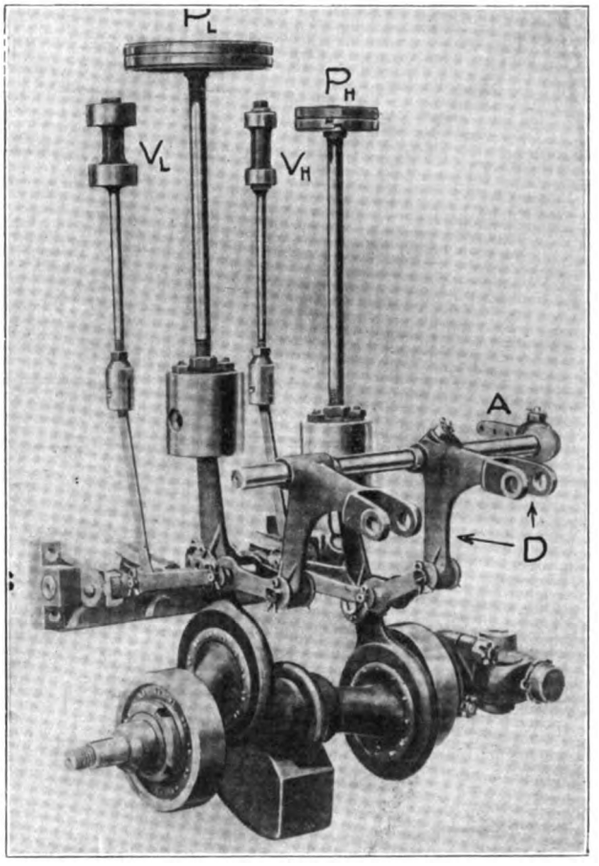
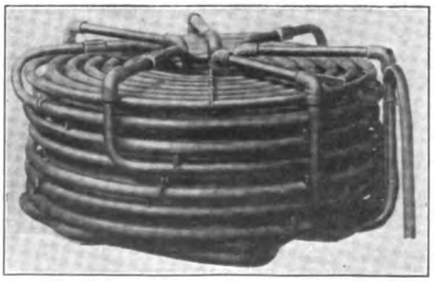
WHITE ADOPTS A NEW ENGINE



Famous Steam Concern to Depart Radically From Its Present Type—Other Features of Its 1909 Product.

As has been the case during the past two years, the White Company, Cleveland, Ohio, will produce two models of the White steamer for the 1909 season. Two new types have been perfected which will bear practically the same relation to one another as the models "K" and "H" of last year, but will differ in this respect that the smaller, which is to be known as model "O," will be essentially a duplicate in design of model "M," but of smaller dimensions and power. The power ratings of the two will be respectively 20 and 40 horsepower. In many respects they will resemble the cars of 1908 and 1907, this being especially true of the generator and regulating devices, which will be identically the same in detail as those of the models current. The engines, however, are of entirely new design, and present a number of features which are radical in automobile construction.

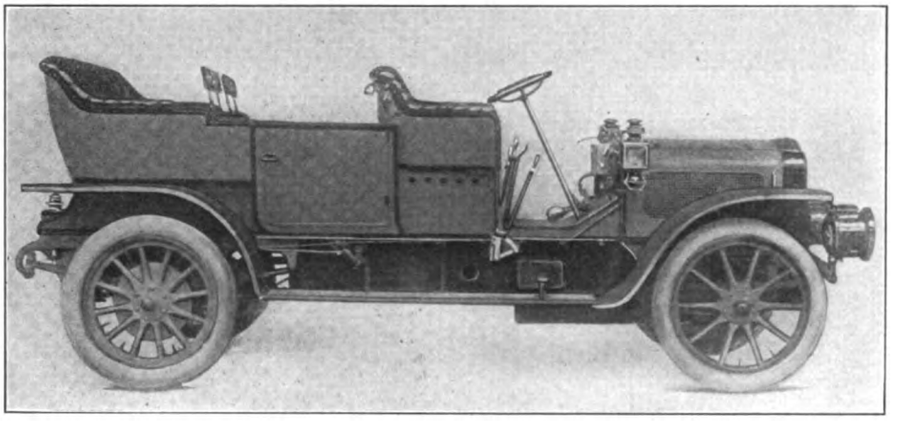
The characteristics of the larger car are: wheel base 122 inches; tires, 36 by 4 and 36 by 5 inches, respectively; body of the straight line, seven passenger type; frame, armored wood, reinforced with nickel steel plates; front axle tubular; springs, 44 and 55 inches long, respectively, front and rear; brakes of the internal-external type, acting on drums mounted on the rear wheels. The over-all specifications of the smaller machine are: wheel base 104 inches; tires, 34 by 3½ inches all around; five-passenger body; pressed steel, heat-treated frame; front axle of I-beam section; springs, 37 and 45 inches long, front and rear, respectively; brakes as in the larger car.



WHITE ENGINE SHOWING PUMP CASINGS UNCOVERED

CRANK SHAFT AND VALVE GEAR OF WHITE ENGINE

The generator, which, with its regulating devices, constitutes what is unquestionably the most efficient and compact producing plant ever devised for locomotive work, comprises merely a close coil of endless tubing of half inch internal diameter, in the present types, and, in the case of the larger car, holding less than one-third of a cubic foot of water and steam. The feed water, which has been previously heated by the engine exhaust, is introduced at the upper part of the system and flowing downward through the heated convolutions of the generator, issues from the superheating coils in the form of highly super-saturated steam. There is thus no great volume of either water or steam in the generator at any one time and consequently practically none of the danger attendant upon the handling of large volumes of steam under pressure. Also, the generation being practically instantaneous, there is practically no limit to its capacity under ordinary circumstances.



WHITE GENERATOR

A very essential requisite to the successful operation of such a system is the method of regulation. The heat supply at the burner, which is to say, the fuel regulation, and the water supply, must be governed in such a way as to produce a rate of water flow and steam generation sensitive and variable enough to satisfy the instant requirements of the motor in the way of power. This regulation is made absolutely automatic by the aid of temperature and pressure actuated devices which control the fuel and water supplies. By an ingenius system a perfect balance is maintained at all times, so that any rise or fall in steam pressure above or below the normal—such as must be caused when the car is stopped

Digitized by Google

or started—is at once followed by alterations in the fuel and water supplies, calculated to compensate exactly for the change and hold the steam pressure constant.

The new engine, which like its predecessor, is of the compound condensing type, is considerably lighter, a great deal simpler, and correspondingly more efficient. Its most striking characteristic is the Joy valve-gear, which replaces the Stephenson link motion formerly employed. In this arrangement, the valve motion is derived from the connecting rods, from which links are taken to sliding blocks which travel in curved guides at one side of the engine casing. The valve connecting rods are coupled to this system at a point outside the guide blocks. The changes of cut-off and reversal of motion are obtained directly by altering the inclination of the guides, and the system is so designed that any alteration of the "cut-off" does not affect the "lead" of the valves, so that the engine runs as smoothly under these conditions as with full steam admission. The new arrangement does away with all eccentrics, and permits a reduction in the number of working parts of nearly one-half.

WHITE MODEL M. 40 HORSEPOWER

The accompanying illustrations show the moving parts of the motor grouped in their proper relation, as well as the exterior of the complete motor, showing the covers removed from the pump casings exposing the actuating gear. The method of connecting the pistons Pl-Ph to the double-throw crank shaft, the ball-bearing mounting of the latter, the actuation of the valves Vl-Vh, which are of the piston type with outside exhaust, from the guides, G, as well as the connection of the pump rocker-shaft D to the valve gear, are clearly indicated. The small arm, A, furnishes a driving connection to the oiler which is mounted on the dashboard.

The sprocket on the forward end of the crank shaft is connected by chain to the fan. A novel provision in this arrangement is that of a ratchet drive for the fan whereby the latter is permitted to spin for some little time after the motor has been cut out. As a result of this any reduction in engine speed is not directly communicated to the fan, and the draught is made more nearly constant than would be the case were the fan to follow directly the engine's fluctuations of speed.

The engine frame and casing are in one piece, but the enclosed parts are rendered accessible through cover plates. The crank shaft may be removed from either end. It has but two points of support, and the ball-bearings on the big ends of the connecting rods are so contrived that they may be removed over the ends of the shaft. The engine is supported on two cross members of the frame back of the front axle, and in such a position that the propeller shaft is perfectly horizontal.

The cylinder dimensions of the two types of motor used in the new models differ slightly from those employed in previous models. In the larger engine, the cylinder bores are, respectively, 3½ and 6 inches, instead of 3 and 6 inches, and the stroke is 4½ inches as before. In the smaller engine, the cylinder bores are 2⅓ and 4¼ inches for the high and low pressure cylinders, instead of 3 and 5 inches; and the stroke is 3 inches instead of 3½. As formerly, varying the cut-off and "simpling" are resorted to for heavy road and starting conditions.

Finality Nowhere in Sight, Says Coffin.

The idea that there is any near approach to finality or stagnation, is no part of the belief of H. E. Coffin, vice-president and consulting engineer for the Chalmers-Detroit Motor Co.

"There is no question but that there will be considerable improvement as time goes on in all types of motor cars," says Mr. Coffin, in discussing the subject. "The gasolene driven machine will be no exception. There will be, from year to year, betterments and improvements in many details. Our knowledge of the gas engine is still far from perfect. The steam engine we have had with us for the better part of a century and yet one can scarcely pick up an engineering journal without reading of some experiment or test which has developed new knowledge upon the subject. It is not reasonable to suppose, therefore, that the gas engine can, within ten years, become a perfect mechanism. Unfortunately, also, up to the present time men who have been most thoroughly acquainted with gas engine construction operation have been so busy along manufacturing lines as to be unable to devote much of their time and energy to the development of the finer points of the art. The well designed gas engine has reached a stage which we may term 'commercial perfection,' and we should use even this term advisedly and with reservation. The next few years will unquestionably see marked improvements both in the internal combustion motor itself and in its various accessories."

Where Prominence Has Its Drawbacks.

"It must be very fine to so predominate in your field of manufacturing that when anybody thinks of a 'steam car' they think of the White," said a prominent gasolene car manufacturer a few days ago to Windsor T. White, president of The White Company.

"It is a fine thing and yet there are times when we wish that the public would keep in mind that there are other makes of steam cars," replied Mr. White. "As you well know, in the early days of the industry, a lot of steam automobiles with ordinary boilers, were built by incompetent people. Most of these cars, of course, went to the scrap heap long ago. But every once in a while some one digs up one of these obsolete steamers and fixes it so that it will run. Sooner or later—generally sooner—something happens to this 'steam automobile,' and we are more than likely to get the discredit for it. For example, about two weeks ago an old Geneva steamer blew up near Plainsville, Ohio, with disastrous results. The published reports of the accident spoke of a 'steam machine blowing up' and some people who do not know our car and who, therefore, do not realize that such a thing is an absolute impossibility with the White, thought that one of our machines was involved. If these people had given any thought to the old crude steam cars, they would undoubtedly have placed the blame where it belongs."

One Firm Obtains Complete Monopoly.

By the terms of a contract recently closed with the government of Montenegro the firm of Laurin & Klement, of Jungbunzlau, Bohemia, is given a 15-year monopoly of the supply and operation of public motor vehicles of every sort, both for passenger and luggage transportation. By the terms of the agreement the firm is to open a postal motor service throughout the principality under a government subsidy. The outcome of the project will result in a vast improvement of communication between the Austrian port of Cattaro, and Cetinge, Niksic, Podgorica and other towns of Montenegro.

MUST START PROMPTLY OR REFUND

Washington Strikes at a Trick of the Sight-Seeing Trade—Fares Must be Refunded on Demand.

Sight-seeing automobiles have had a regulation imposed upon them in the city of Washington, which if applied in other localities as well, will quite change the methods ordinarily employed in attracting customers. The district commissioners in the Capital have issued an order requiring sight-seeing automobile companies to refund immediately upon request the fare paid by any passenger whenever the automobile fails to leave the designated starting point within at least 10 minutes after the time announced for departure, and to refund the fare if the trip be not completed.

For some time it has been the practice of the sight-seeing companies to have cars standing at different points collecting waiting passengers until enough were secured to make one good load, when the victims would be gathered by the one machine and crowded together into a single trip. Alluring signs in white chalk about the next trip starting at such-and-such a time and the big machine standing apparently ready with plenty of desirable seats and lots of room to spare, would trick the innocent visitor into clambering aboard and figuring himself very lucky. But after waiting sometimes for hours after the time scheduled for departure and then being compelled to leave the car in which he was seated, to be crowded aboard another which would heave alongside already full, the visitor would often be exceeding wroth, but any efforts that he would make to get his money back would meet the derisive ha-ha. Complaints on this score grew to a point where the commissioners felt called upon to take action, the offense being one of long standing and one that is not confined to Washington.

In appearing before the commissioners in connection with a complaint of this character, F. W. Niles, manager of one of the companies, informed the authorities that he had not refused to refund the money, but that he told the aggrieved customers that the matter would have to take the regular course through the general offices in New York, just as in the case of refunds on railroad tickets. The new regulation will compel immediate cash adjustment.

Fire Chief Says Horse is Doomed.

In spite of the sentiment surrounding the much beloved, sugar eating fire horse, which is groomed and petted by the men of the department and admired by the public, the animal will have to give way to automobile fire apparatus, according to Chief James Horan, of the Chicago fire department, who expressed his views in a speech at the closing session of the eleventh annual convention of the National Association of Firemen, in Chicago last Saturday. The chief sees in the successful performance of motor fire engines, trucks and hose carts all over the country, the certain supplanting of the horse.

"The fire marshal now is, indeed, to be commended if his fire appliances of to-day are not ready for the scrap pile next year," said Horan. "We are living in a gasolene age and all the mechanical engineers are unanimously of the opinion that the horse-drawn fire apparatus has seen its day. With the advent of the automobile it is apparent that the five ton engine and the seven ton truck, the two ton hose wagon and the chemical engine, will before many moons be things of the past, and the ever faithful horse, that eats its head off 365 days and nights of the year, must also be relegated to the historic past."

"Wreckers," and How They Work.

Cruising automobile "wreckers," which are nothing more or less than repair cars equipped with spare cans of gasolene, some tubes and casings of various sizes, emergency tools and towing ropes, are one of the latest developments along the most used motor car highways in and around New York City. They are on the lookout for machines that are en panne, and in some cases they actually follow a car for miles in anticipation of a breakdown, the likelihood of which has been made manifest by the sound of the mechanism or some external symptom.

Needless to say, the charges made by the experts of the cruising "wrecker" are sufficiently steep to make up all deficiencies growing out of the long waits between customers, and as the touring automobilists are generally heavy with cash, the cruisers are able to get liberal compensation for the work they do, exercising an acute commercial judgment in deciding whether the disabled machine can be repaired on the road with the tools at hand or whether a long tow back to the repair shop will be necessary.

Motor Wagons for French Army.

Automobiles will be used in connection with the commissary department of the French army if the request of the minister of war, who has asked the French Chambre Syndicate de l'Automobile to arrange to loan the army 80 motor trucks, is granted. It is desired to use the trucks during the forthcoming military manoeuvres in the Blois, Tours and Bourges districts.

Road Train for Russian Royalty.

One of the latest acquisitions of European royalty is a Renard road train, which has been put into the service of the Czar for the transportation of the baggage of the Imperial Court of Russia from point to point. The first train, which was purchased for the Imperial garage in May last, has proved so successful that a second is to be installed.

HAY DEALERS RECEIVE A WARNING

At Their Convention They are Told that Hay Market is Contracting Owing to Use of Automobiles.

A headline in a newspaper published in the city of Toledo, O., reads, "Autos Agitate Hay Dealers," from which one might infer that autos eat hay. This idea would be indeed erroneous, for while cars have been known to try to climb trees, dig up roots and herbs, plunge into shady pools and pluck pond lilies, and do other "stunts," subject to the weather's effect on their natures, no automobile has ever been known to eat hay, either dried or new-mown.

But out in Sandusky, O., nevertheless, the invasion of the automobile is giving the foremost folks of the hay industry veritable hay fever and is roiling them considerably. They held a convention and elected new officers and made speeches and things. Ex-President H. C. Morgan, of the National Hay Association, delivered a hot line of talk in an "ain't is awful, Mabel?" tone, when a timely discussion of the live topic of "The Automobile vs. the Horse," was in progress. Said he: "I want to warn you!" just like that—and then he proceeded as a hay dealer, to warn his fellow members that the market for low grade hay is disappearing with the increase of motor cars. "City folks," he declared, "are using gasolene buggies in place of the hay-fed eqyne!" and then he went further to state that while the market for high priced hay is improving, a new market for cheap hay must be found! New breakfast food factory accounts must be solicited, perhaps. All of which clearly goes to show what ravages the motor car can work.

On the other hand, the straw market doubtless will improve, for, not to mention straw bail, automobile straw rides are becoming fashionable. Around Deal, N. J., and Asbury Park, these affairs are finding much popular favor, so this may help to even up things.

To Curtail Use of High Power Cars.

As a result of the recent scorching and smashup of E. Russell Thomas, at Long Branch, N. J., other motorists will have to suffer. Commissioner J. B. R. Smith, of the department of motor vehicles of the State of New Jersey, has instructed all agents of his department to cease issuing licenses for cars of more than 65 horsepower. The Commissioner reserves for himself the right to grant such permits. This means that an owner of a Thomas "70" or any other high powered stock model touring cars, particularly six-cylinder machines, will have difficulty in obtaining licenses. It is understood that in most cases, according to the commissioner's plans, the high powered cars will not be licensed at all.

MAYOR HAS A RED LIGHT SCHEME

He Would Have Warning Beacons at Danger Points—Thinks Life Insurance Companies Might Maintain Them.

The mayor of Providence, R. I., has a new "life insurance plan," as he terms it, which concerns motorists on Rhode Island roads. In his opinion, life insurance companies should contribute funds towards making the lives of automobilists safe on the highways. He is in favor of a movement to erect danger posts at hazardous curves and cross roads near Providence and elsewhere in the State, at the expense of life insurance corporations, or millionaire motorists.

"I would suggest," said he, "that numerous white posts be erected at the many danger spots, bearing large red signs that can be discerned at a safe distance from all directions, the posts to bear red lamps and be kept burning all night. The signs now in use are frail and placed so near the ground that many persons do not distinguish them from the ordinary real estate 'For sale' sign, until close arrival at the spot. Objection may be made to the cost, but if the pecuniary value of life could be computed, the expense could easily be subscribed by the millionaire auto owners as life insurance for themselves and the public. Life insurance companies might contribute for protection against the maturity of large policies carried by the rich, reckless auto owners. Such contributions would be good investments."

The mayor's plan is a good one, but it is difficult to fancy a life insurance company parting with any cash unless forced to do so.

Why He Willed His Money to Ballooning.

One of Jersey City's oldest inhabitants, the late Jeremiah Carihanne was no lover of automobiles and he carried his hatred even to the grave. The manifestation of his aversion for them in his last days was most interesting, for out of the ashes of his smouldering dislike, has arisen that which will benefit science, particularly as regards the perfection of vehicles of another sort. He willed his all to the cause of ballooning and aerial navigation, and gave his remarkable reason for it, too.

Upon his death, it was ascertained that Jeremiah was insured for $500. An envelope was found in his room containing his last will and testament, which has just been made public. After giving directions for his funeral, he wrote:

"Knowing from bitter experience what it means to be crippled from rheumatism and be forced to flee from the path of automobiles, I hereby bestow what is left of the insurance money on some man who is trying to perfect an airship, so that there will ultimately be less running about the streets and more flying through the air. I hereby appoint my executor as the man who will decide who is to get the money."

Edward R. Doyle is the executor and he says he will endeavor to carry out Carrihanne's request. The amount he has in his possession is $350.

Making Ready to Expel Scorcher Thomas.

In order to expel E. Russell Thomas, the New York banker, from the New Jersey Automobile Club, the trustees of that organization went to the trouble of calling a special meeting on Tuesday evening of this week. Thomas, who recently drove Harry Levey's 120 horsepower Vanderbilt cup racer on Ocean avenue, Long Branch, at a speed very near the powerful car's full capacity, and at a street corner struck a carriage, smashing it to splinters, killing a team of horses and injuring several people slightly and himself seriously, is at present confined to a sick bed. The club has given him eight days in which to make a reply to its action, and unless he chooses to demand a special hearing, he will be ousted at the next regular meeting of this club on September 14. Inasmuch as Mr. Thomas has repeatedly violated speed laws, a practice that this club is endeavoring to abolish in New Jersey, the members of the organization feel justified in demanding his expulsion.

Real Endurance Run for Kansans.

Elaborate preparations are being made by the Kansas City Automobile Club for its endurance run to be held September 20-30. The route has been outlined and Elliott H. Jones, with a party in a Studebaker car, are out doing the "pathfinding." The proposed itinerary starts at Kansas City, Mo., and jumps over into Kansas, then south via Wichita into Oklahoma, turning at Oklahoma City and running back to the starting place by a different route. The distance will be 875 miles, and the plan is to run about 125 miles per day. The contest will be conducted along the lines of the Glidden tour, with the agony of that event eliminated. The Kansas City Star will award a trophy to the winner. A. A. A. rules will govern the affair.

Denver Offers Half of Entry Fees.

As a special bait to attract entries for their 300 miles stock car race on Labor Day, the newly organized Denver Motor Club has announced that the contestant finishing the race in the short elapsed time will receive a prize amounting to one-half the total amount of entrance fees. This sum will be presented in gold coin and in view of the fact that there are already ten entries at $100 each, the club expects about as many more before the list is closed. The new Colorado organization recently affiliated with the Three A's and the coming contest will be run under A. A. A. sanction and rules.

"RESTRICTED LICENSES" BY MAIL

Massachusetts Unbends Slightly in Its Attitude Toward Non-Residents—How the New Scheme is Operated.

The Massachusetts Highway Commission has solved a problem in connection with licensing non-resident drivers, which is said to be working satisfactorily. Until recently, there has been much trouble experienced by motorists desiring to tour through Massachusetts, owing to delays and red tape incident to registration.

Most of the trouble in such cases was in getting to a place to take out a license without being caught by a policeman and hauled up for not having the license. The commission, under the law allowing it to place restrictions on registrations has now decided to issue certain licenses in response to application by mail, the license to become void unless the operator passes a Massachusetts examiner before the end of the stated number of days, as set forth in the preliminary certificate.

Under this arrangement, when a New Yorker or any other non-resident prepares for an automobile trip into Massachusetts, he will merely write to the commission giving a brief statement of his plans and qualifications. In response the board will send him a "restricted license," on authority of which he will enter the State with his car and operate until he takes the examination. If he passes, the license will be perpetuated, otherwise not.

Kentucky Has Visions of a Motordrome.

That Blue Grass State, which for years has been famed for its love of equine sport, has recently manifested some interest in motor racing at Lexington and elsewhere. In fact, if the ideas of Congressman Joseph Rhinock, president of the Latonia Jockey Club, Vice-President Harvey Meyers, and John J. Ryan, the former track plunger, take shape, Kentucky will become a center of motoring interest, for the three men propose building the first oval track in America exclusively for automobile racing. They contemplate having a saucer constructed along the lines of the Brooklands course in England, that will be 1⅝ miles around, with the turns banked to permit high speed. It will probably be erected on the shores of Licking River. Regular automobile meetings will be held and purses hung up similar to horse races and from the plans laid out, these purses will be of such alluring denominations that the fastest machines and best drivers in the country will be seen there within the next year or so—all of which, however, is in the nature of counting chickens a very long time before they are hatched. Several hundred motordromes already have been constructed—in American imaginations.

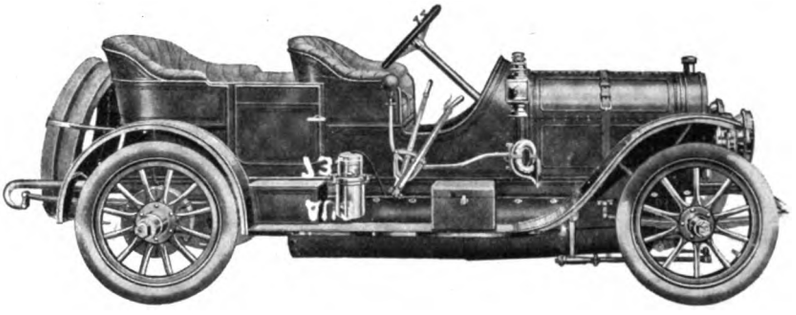
NEW FEATURES OF POPE-HARTFORD

Many Refinements in 1909 Models—Novelty in Brakes, Clutch and Torque Rod—Striking Body Designs.

Following the same general lines as those of its immediate predecessors, the specifications of the Model "S" Pope-Hartford car, which is to be the 1909 product of the Pope Mfg. Co.'s Hartford (Conn.) plant, have just been announced. Embodying as they do several new and improved structural details while retaining the qualities which have proved most satisfactory up to the present time, the machine seems destined to become a worthy successor to those which have made an undeniable mark in the field during the past two years.

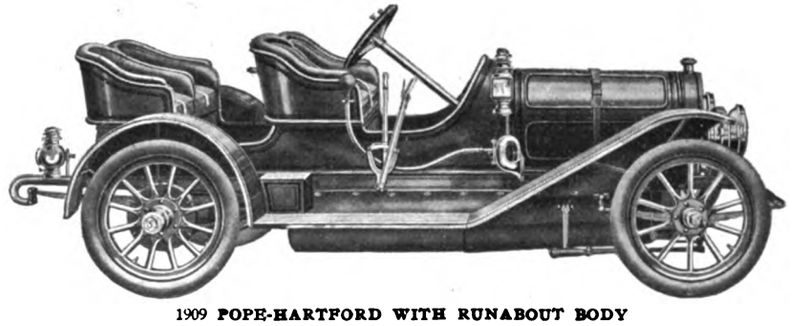


Certain of the characteristics of the 1908 model are retained exactly, or with slight modification. Thus the armored wood frame, the power plant being mounted on a pressed steel sub-frame, is retained, with the slight exception of a new form of rear spring hanger. The so-called "goose-neck" type is now to be employed, its requirement

1909 POPE-HARTFORD STANDARD TONNEAU

being in part, the use of longer springs than before, the rear suspension members being 56 instead of 52 inches long. The springs are now swiveled upon the rear axle tubing instead of being perched in fixed relation to it, thus allowing for any possible tilting of the torque and drive groups as might result from excessive braking or driving strains without straining the spring connections. The overhead valve type of motor is retained, though in entirely redesigned form, and the characteristic radiator profile remains unchanged, despite an alteration in the construction of the hood. The latter in the new model will be made without doors, will be straight sided, instead of having the double curvature of the sides, and will have a new method of attachment. Similarly the mud guards follow the lines already used, but with the addition of leather splash guards between the fenders and the frame line. In body design an entire alteration has been made.

The new touring body is of the straight line type, is much roomier than that of the Model "M", having 4 inches more floor and 1½ inches greater width and depth of seat. The straight type of dash has been adopted, and the finish and trimming is of improved form. Two variations in body design are made possible by the design of runabout and "pony tonneau" bodies, both also of new construction. In the former, the engine is mounted farther back than in the touring car, necessitating some slight alteration in the details of the transmission, and



1909 POPE-HARTFORD WITH PONY TONNEAU

the steering column is given a greater inclination. This, coupled wth the increased length of hood, gives a totally different appearance to the machine from that of the touring model, although its wheel base is the same. The second variation is made possible by the use of a very light, low-backed tonneau body, the rear seat of which is placed well forward to give room at the back for tire irons and other equipment. The mounting of the dash is the same as in the case of the runabout, while the lines of the body may be described as a condensed version of those of the touring car proper.

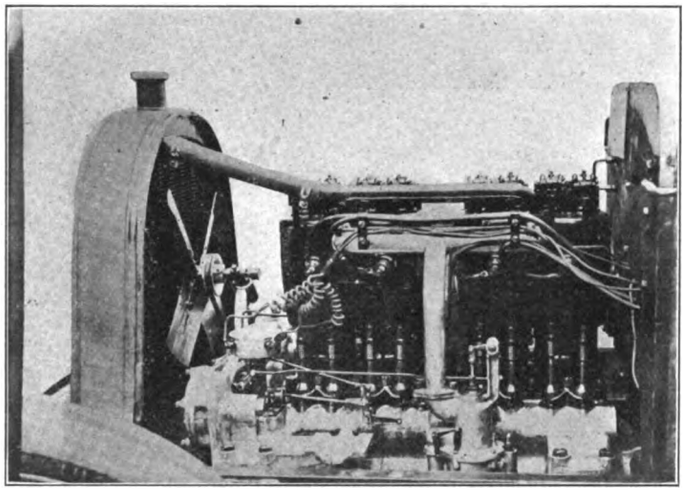
In the power plant, a complete overhauling of the design has resulted in a number of minor improvements and the introduction of several features which are of striking merit. The motor, which like that of the Model "M" car is rated at 30 horsepower, has cylinders which are similar in form to those employed on that model, but mounted in the reverse position. Thus the exhaust is now on the right side of the machine, together with the oiler and water pump—both driven by a line shaft from the forward gear housing, while upon the opposite side is the carburetter, while just forward of it is the bracket upon which the magneto is mounted. Adjacent to this is the timer shaft, which is vertical and driven from the two-to-one group by means of spiral gears. The timer is mounted on a substantial pillar and is raised sufficiently above the level of the crank case to be thoroughly accessible.

The forward end of the crank case has been changed so as to permit of the complete housing of all gears integrally with the main case, and their lubrication by oil baths, fed by the splash of the cranks. A new method of fan mounting also has been provided an ingenius provision for automatic tensioning of the drive being included. The crank shaft has been enlarged and all its bearings lengthened, and this, together with the adoption of special white brass bushings, combines to render the working of the engine at once more reliable and less subject to vibration. The cam shaft and all gears may now be removed without removing the engine from the frame.

The control mechanism leading from the steering wheel to the carburetter, timer and magneto, is neatly arranged in the form of telescopic rods, running across the case in front of the cylinders. The carburetter, which is given a particularly accessible location, is of entirely new design, though following the style used in the current models,

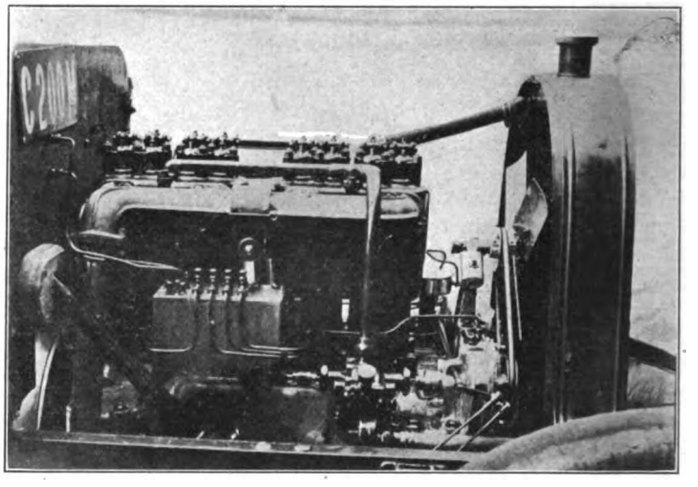
1909 POPE-HARTFORD WITH RUNABOUT BODY

Digitized by Google



is of the central draught type, and has been worked out with special regard to facility of starting and freedom from flooding tendencies.

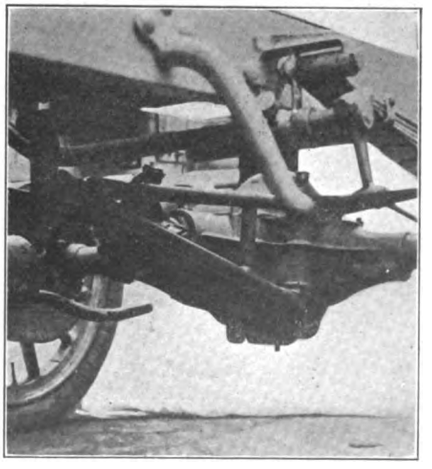
Altering the arrangement of the motor has involved a rearrangement of the piping, the new groups being of simple and unobstrusive form, and free from abrupt bends. The cam shaft is mounted on the left side and the rocker method of actuation by means of tappets and overhead arms is retained. The valves, however, are made larger, and with lower lift, in order to secure more silent operation and better freedom of movement for the gases.



The transmission includes an entirely new clutch, which though of the plain cone type, as was used in the previous model, is of 1¼-inch greater diameter, and is given an entirely original mounting which is calculated to do away with any possible tendency to disalignment with the fly wheel, and to render the action of engagement perfectly even and gradual at all times. The manner in which this is brought about is worthy of special attention. An important feature of the clutch also is the provision for adjustment of any possible wear in the universal coupling which connects it to the driving shaft of the change gear.

The gearset, which is practically the same as that previously employed, is of the selective type and actuated in the conventional manner, all the controling mechanism being enclosed in the gear case. The propeller shaft carries the service brake just back of the case, this being of the contracting type and mounted on a pressed steel drum of 2¼ inches face by 12½ inches diameter. The propeller shaft is equipped with two universal joints and a slip joint—the latter at its forward end, and the rear axle group is of the full floating type, with hub-cap drive of improved and secured pattern. Enlarged Timken roller bearings are used in mounting the bevel gears, and a new method of adjustment is provided for the driving bevel, whereby in assembling an exact adjustment of mesh may be obtained, to secure the least possible resistance and noise in operation.

Except for the clutch and braking devices, the most unique feature of the machine is the torque resisting mechanism in which the usual torsion rod or stay is replaced by a tubular support of trussed triangular form, supported at its forward end by means of a ball and socket joint upon hinged bracket where it is cushioned by buffer springs. In order to carry this, a new tie member has been introduced in the frame, so that the rear gear case support no longer carries any but the dead load of the gearset. This new member, also serves a useful purpose in tying the sides of the frame together.



LEFT SIDE OF MOTOR, SHOWING CARBURETTER

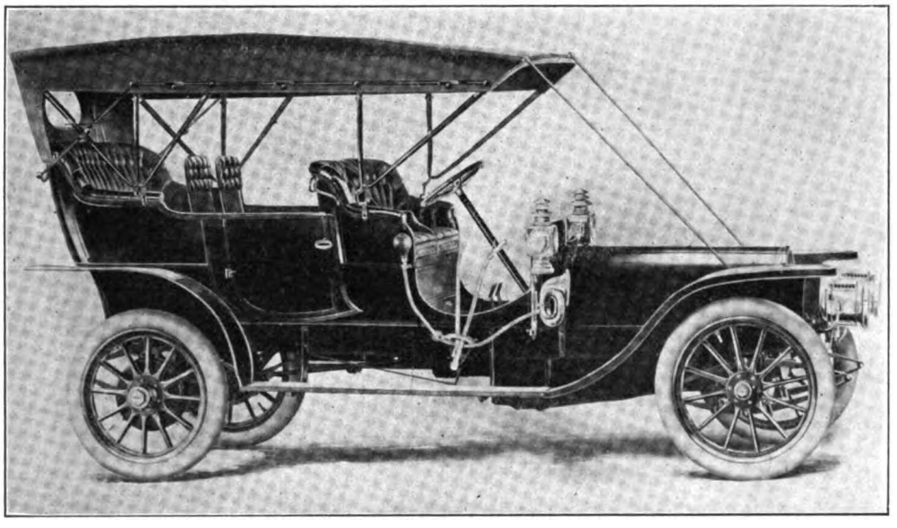
RIGHT SIDE OF MOTOR, SHOWING OILER AND WATER PUMP

The rear end of the torque member instead of being rigidly attached to the differential housing, as is ordinarily the case, is swiveled to it by means of a vertical pin, the connection being provided—like every other part of the mechanism where motion is to be expected—with a grease cup. The effect of this is to prevent cramping in the member due to any side swaying of the frame on the springs, or due to any possible transverse movement in the rear axle such as might result from heavy skidding thrusts. The traction drag is taken by the forward ends of the rear springs, by which the fore and aft relation of the axle is preserved. With the swivelling of the springs on the axle tubing, and the absolutely universal attachment of the torque member, which, as indicated by the accompanying illustration, is very strong, despite its light construction, it is practically impossible to conceive of any possible spring motion to which the transmission will not adapt itself without distorsion and without interference with its proper function.

NEW HINGED TORQUE ROD

The rear wheel braking equipment is new, the retarding action taking effect through the hubs instead of the flanges, as is more commonly the case. The diameers of the drums have been increased to 14½ inches diameter, and are actuated by toggle mechanism of very powerful as well as positive action.

The Mounting of Outside Splashers.



Consideration for appearances has led many drivers to mount splash guards on the inner side of the wheels of their cars, these taking the form of short curtains of canvas or leather to prevent the mud and water flying up on the under body and mechanism of the machine. Because of the axles, it has not been difficult to locate such devices on the inner side of the wheels, but until recently no simple method of applying similar guards to the outer edge of the wheels, for the benefit of pedestrians and other traffic, had been found. The protection of others from splashing which outside guards afford is possible of realization, however, as several devices of this character have been developed. In one type, the guard, which consists of a swinging screen of chain cloth, hangs on a plate with a bearing encircling the wheel hub. The bearing supports the floating plate, from the lower part of which the screen is suspended while the upper part is connected to the frame of the car with a long, yielding spiral spring, which holds it in position.

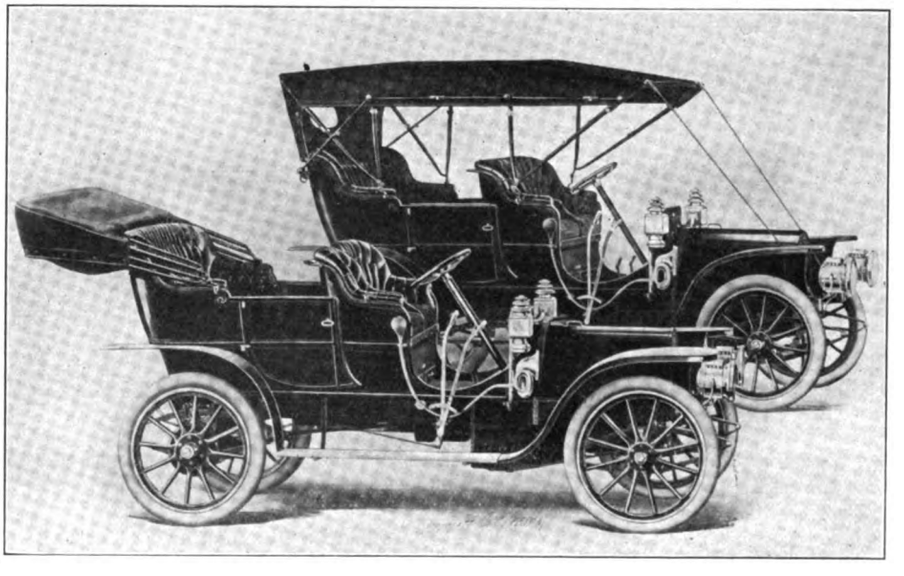
NEWNESS IN THE 1909 FRANKLINS

Refinement Rather than Marked Changes the Rule—Governors and Battery Ignition are Eliminated.



It is significant of the successful operation in actual service of that radical arrangement, the concentric valve gear, that it is to be embodied in the 1909 models of the Franklin cars, as in those of the present season. Another original feature which also is to be retained without material alteration is the auxiliary exhaust at the bases of the cylinders. Indeed, the characteristics of the new models which have just been announced by the H. H. Franklin Manufacturing Co., Syracuse, N. Y., are essentially the same as those of the models now in use. That does not necessarily imply, however, that the 1909 line will be without novelty, nor that it does not differ in a number of respects from that of 1908.

1909 FRANKLIN "SIX", 42 HORSEPOWER

The new Model "G" car, for example, is equipped with an 18 horsepower motor instead of one rated at 16 horsepower. Its dimensions are 3⅜ by 4 inches, bore and stroke. It is built on similar lines to the 28 and 43 horsepower, four and six-cylinder motors, but on a reduced scale. It is a slower running engine, fitted with a front air fan and is slightly reduced in weight. A small increase in wheel base has been brought about in this model as a result of the introduction of wheels of 2 inches greater diameter than heretofore. The wheels are now 32 inches in diameter, shod with 3½ inch tires. The body length also has been increased and is correspondingly more roomy and comfortable. The car is furnished with runabout, touring, landaulet and brougham bodies—the latter being similar in design to those employed on the 28 horsepower car.

Type "D" is the largest four-cylinder car in the line, and is driven by a 4¼ by 4-inch motor, as was the case in the previous model of the same power. Like that of the smaller car, it is equipped with Bosch high-tension magneto but is not furnished with the battery, coil and timer equipment which complete the "double ignition" system formerly employed. The wheel sizes on this model also have been increased by 2 inches, and now are 36 inches diameter. As equipped with the landaulet body, however, this model runs on 32 inch wheels, as being more suitable for town car service. The design of the regular touring and runabout bodies conform to the lines of the six-cylinder models, but they are lighter and smaller to match the lower power of the motor.

1909 FRANKLIN 4 CYLINDER, 28 HORSEPOWER

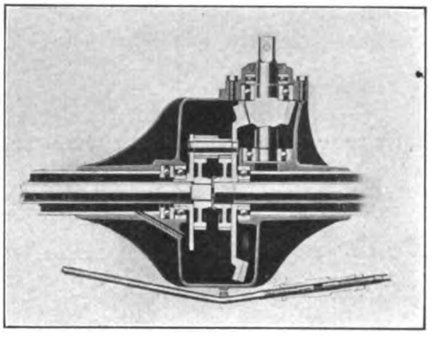
The six-cylinder model, which is known as type "H," which is the largest car produced by the Franklin Co., is made in three styles of body mounting, namely a seven-passenger touring car, single or double rumble runabout, and seven-passenger limousine. In this model also, is to be found a new type of steering gear, of original design, and of the worm gear type. It is designed to do away entirely with lost motion and replaces the bevel gear type formerly employed on this, and still used on the other models. The wheel base of this type is 127 inches, and its catalog weight is only 2,500 pounds.

Significant of improved methods of carburation is the fact that the governor which has been used on all models heretofore is done away with in the production of the 1909 types. In this connection it should be noted that a change has been made in the position of the carburetter by reversing it, thus adding to the hill climbing ability of the cars as well as improving their response to the demands of service. On the model "H" car, the crank shaft has been redesigned, and is now larger and stiffer than before. On this motor, also, the magneto action is governed by an automatic regulator which has expanding arms pressing against the periphery of the driving gear. The wiring, it should be observed, is led through protected conduits and is thus guarded against chafing and short circuiting as a result of external injury. Another improvement is in the arrangement of the front cheek piece, which may be removed without disturbing the cam shaft. The latter also may be dismounted without interfering with the cheek piece. The attachment of the starting crank has been made waterproof also, and is held in place by a leather stirrup. Several parts have been eliminated and others simplified as a result of doing away with the timer. The motors are thus lighter and otherwise improved in consequence of the "going over" which they have received.

As already indicated, the concentric valve construction which was introduced at the beginning of the present year, as well as the auxiliary exhaust which has been a Franklin feature for several years, is retained. The inlet and exhaust valves being superposed, a true dome-shaped cylinder

Digitized by Google

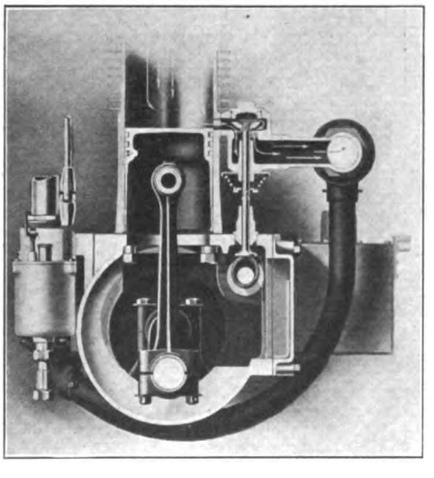
is made possible, with the result that the area of the inner cylinder wall is reduced while the exterior and heat radiating surface is practically unaltered. In consequence of this, the cooling effect is increased. Because the inlet from the manifold is more direct than is possible with the more conventional method of cylinder formation, it also follows that there is less friction to impede the flow of the gas, and a larger charge can be taken in with the same valve area than otherwise would be possible. As the intake valve is well cooled by direct contact with the cylinder head, some little advantage is gained through the reduced expansion of the entering sea.



In the type "H" motor an improved method of suspension is employed. The cross rails of the frame are made of angle steel and also support the magneto and oiler in such a way as to reduce vibration to a minimum. Another new feature is the "double heat accumulator," which is used in securing the warm air supply for the carburetter. This consists of a jacket surrounding the auxiliary exhaust pipe with a leader running around and below the engine base to the carburetter, which is mounted on the opposite side. This intake jacket is purely an addition to the steel warm air collector used on the other models. A change in the style and position of the oiler also has been brought about. The Hancock, positive feed, gear driven device is now employed, and it is placed directly against the engine base in such a position that it is maintained at uniform temperature regardless of weather conditions. It is more accessibly placed than before, and is given plenty of free space, so that adjustments may be made readily.

As was the case with the previous models, the two larger cars of the new series will be equipped with selective type transmissions, and the smaller with the "self-finding" gear shift which already is familiar to users of this car. With the selective type of lever, the arrangement is such that whenever the vertical position is assumed, the neutral is automatically secured by means of spring tension. No gridiron plate is used, and the forward and reverse relations are obtained by pressing the lever inward or outward as the case may be when throwing it out of the vertical position. The arrangement of gears and connections is such that it is said to be possible to shift from one gear to another without declutching.

No spark lever is necessary to the control mechanism of the Model "G" cars, because of the automatic spark regulator. The spark levers used on the other two models, however, are retained in position by a new device, doing away with the ratchet arrangement used on the current models.



The use of an auxiliary fuel tank is another new feature of the forthcoming models. It is so contrived as to be filled automatically when replenishing the main supply, but cannot be used in the engine until the larger quantity has been entirely used. It is then necessary to turn a three-way cock located on the outside of the frame underneath the driver's seat. This also is an added fitting and supplies means of cutting off all fuel flow in its third position.

Among other alterations may be mentioned the use of Timken roller bearings in the front wheels of all models, the use

1909 FRANKLIN DIFFERENTIAL GEAR

of plain bearings on the steering gears, instead of ball bearings; the use of extensions on the front mud guards so contrived as to prevent the spattering of the motor through the grilled front of the hood; the lengthening out of the engine boot and the elimination of the transmission boot; and a slight change in the method of housing the differential in which rivets have been made to supplant bolts and nuts. Braking

FRANKLIN "DOUBLE HEAT ACCUMULATOR"

areas have been increased, and an anti-rattling device adopted, three-piece toe boards of cast aluminum have been installed, slight changes have been made in the method of constructing the tops, and many finishings which formerly were polished bright are now given a dull finish in assent to the growing demand for the elimination of tawdry trappings on the machine.

Draught Injures Body Finish.

Because the body finish on the average motor car proves to be of anything less durable than that of the average horse-drawn carriage, it is frequently charged that less care is exercised in finishing cars than has been the custom with carriage makers. As a matter of fact this belief, which is in many respects erroneous, fails to account for the extra wear which is brought upon the automobile body through the effect of the fierce impact of the dust and sand which is thrown up by the windage of the car. This takes effect most noticeably on the rear body panel, where the suction of the draught created by the machine itself causes a constant play of dust upon the finished surface. It is the same in its effect as the sand blasts of commercial application, and is charged with much of the same abrasive.

Why Sub-Frames Require Inspection.

In cars which have the power plant mounted on a sub-frame, it is essential that the position and alignment of the latter should be investigated carefully at each periodical inspection. If the frame is too light for its work, or is insecurely fastened, there is danger that it may warp out of line when unduly strained. Although it is customary to provide flexible or universal joints at all points which might be affected by such a disarrangement, the result throws an abnormal amount of labor on the parts of the joints, and causes an extra amount of friction on the transmission producing loss of power. Besides this, the condition may indicate a dangerous weakness in some quarter.

One Cause of Short-Circuiting.

It is quite essential that the fiber racks which are so commonly employed to secure the secondary wiring of the ignition system to the tops of the cylinders, be kept in good order as otherwise there is danger of the wires sagging against the cylinder heads and causing short circuits after the insulation has burned partially away. Difficulty in this quarter is especially apt to result when the wiring has been dismounted a number of times and the screws which hold it down have worn in their holes and become loose. When this is the case, new screws of a larger size should be substituted for the original ones.

How Threads Frequently are Stripped.

It is all very well to attempt to start a refractory nut by slipping a short length of iron pipe over the handle of the wrench. The practice should not be indulged in when drawing up bolts or nuts, however. Generally speaking, the average forked wrench is designed to give a safe leverage over the standard nut which it is made to fit. Increasing the leverage over this amount, and so increasing the pressure brought to bear upon the nut, is almost certain to strip the threads.

Where electric lamps are used for the dash and tail lights of the car they should be wired in series. By this means an effective indication is secured to show whether the rear light is burning properly.

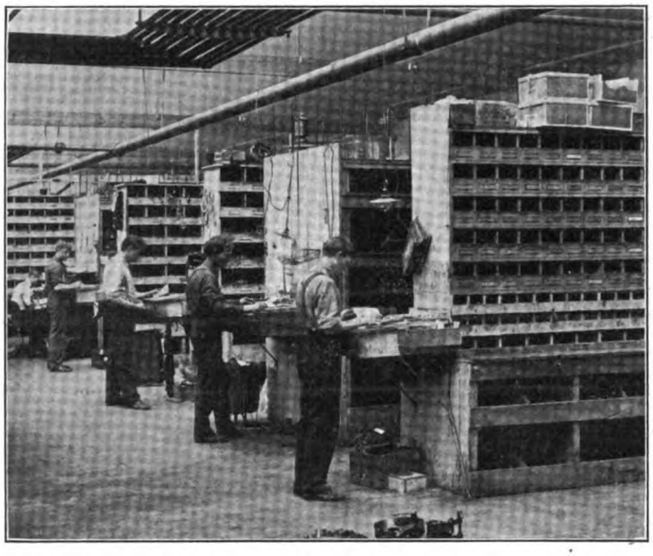
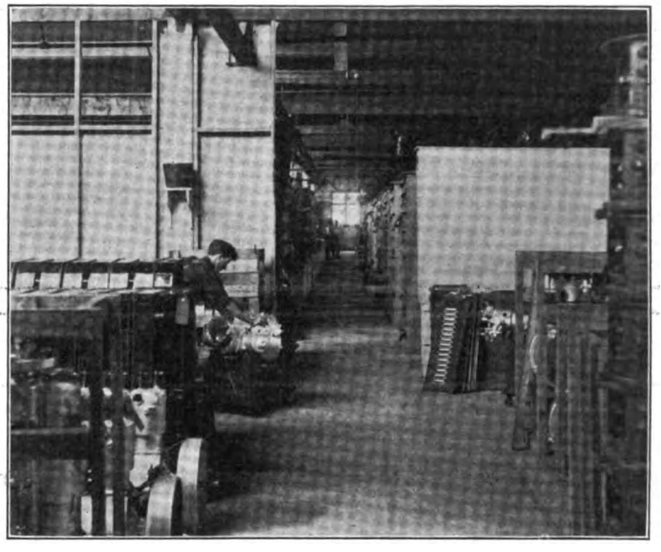
ABOUT FILLING ORDERS FOR PARTS

Apt Illustration of the Immensity of the Task—System in Vogue in One of the Big Factories.



System and dispatch in the filling of orders for parts is now recognized as one of the chief necessities in the best equipped automobile factories, and though all manufacturers see the wisdom for the convenience and satisfaction of their patrons, few have developed the system which makes it possible to supply within 24 hours a duplicate of any part of any car ever built in that factory. Of the few is the firm of Thomas B. Jeffery & Co., who have on hand a duplicate of every part of every Rambler ever manufactured since 1902, and they make the claim that they can ship replacements on the same day the order reaches the factory. Such promptness is due to the organization of the sundry department. Orders are received by the parts order department and sent to the sundry department for filling. Here the parts ordered are inspected by two men to insure accuracy. Again, in the shipping room, the order is time-stamped and double checked to avoid mixing orders in packing. Parts of each and every piece ever used in any Rambler car are carried in stock; the manner in which they are stored and kept track of is shown by the accompanying illustrations.



The sundry department has 2,288 square feet of floor space and has 1,500 bins of various sizes, all arranged in sections 8 feet in height. In this room is found only such parts as are most frequently in demand, while in a reserve stock room, with 3,280 square feet of floor space, other parts are kept.

In addition there is the annex, motor stock, transmission stock and axle stock rooms, having a combined floor space of 5,210 square feet.

In the Rambler Parts List there are nearly 8,000 distinct parts, these covering, of course, all models built since 1902, a fact which conveys an idea of the immensity and comprehensiveness of the system.

The fact that there are 14,000 Rambler cars in use, many of them now in their fifth and sixth year of service, makes the equipment of this department very valuable to owners, while the fact that all Rambler parts are made in the Rambler factory enables this company to sell repair parts at astoundingly low figures. Although repair parts may not be needed during the first or second season of operation, this company sees the wisdom of manufacturing and keeping on hand extra parts of all models so that in years to come owners may procure them without delay and at reasonable cost.

TWO VIEWS OF STOCK ROOM AT RAMBLER FACTORY

Scavenging the Motor While Driving.

When driving on open roads no possible opportunity should be lost of scavenging out the cylinders by closing the throttle on down grades and permitting the machine to coast while pure air is drawn into the cylinders. This cools and cleans them at the same time, besides, in the more modern type of cars, providing a slight economy of fuel. The eager rush of the motor after the scavenging period is sufficient proof in itself that it is a beneficial practice.

When an Old Motor Becomes Cranky.

A frequent source of annoyance in the running of a motor which has seen considerable service arises from the lost motion between the connections of the throttle and ignition levers and subjoined parts. In most cases this may be corrected by inserting a tension spring in some portion of the system in such a way it will keep the parts constantly drawn in one direction. Any slackness of the joints will thus be obviated.

ADAPTING AUTOGENOUS WELDING

Brooklyn Man Develops System Using Ordinary Gas and Atmospheric Air—Results of Tests.

As a process approximating the oxy-acetylene method of autogenous welding, but having advantages in economy by the use of ordinary illuminating gas and atmospheric air instead of tanked oxygen and acetylene, a new system, the invention of A. K. Schaap, was given a demonstration last Friday at the garage of the Schaap Automobile Co., Brooklyn, N. Y. The heat attained under Schaap's system is claimed to be in the neighborhood of 4.500 degrees and is sufficient to weld or cut metals much as the acetylene flame does. Like the oxy-acetylene system, the application of the heat can be confined to the area to be treated.

While the use of gas with air under pressure is not altogether new, Schaap's method presents novelty in that the gas and the air have a preliminary mixing before being conducted to the burner where the final combination of air and gas is made. There are thus two points at which the air is carburetted with the gas. In one combination the air is used at a pressure of about one pound while in another it is used at 30 pounds. The gas is used at the pressure at which it ordinarily comes from the meter, which in the case of the tests was something over an ounce. In the course of the demonstration Schaap showed how quickly his flame would cut through an inch thick steel plate, and perform welding and cutting wonders under water. The inventor does not claim to be able to attain as high a heat as with the acetylene flame, which is in the neighborhood of 6,300 degrees, but is satisfied that it is sufficient to meet all ordinary requirements.

Mathematics for Minneapolis Climb.

Saturday, August 29th, is the date that motor enthusiasts of Minneapolis, Minn., have decided to hold a climb on Columbia Heights, or another suitable location, and plans for running it have been announced. Cars will be divided into seven classes and the winners in five of these will be determined by formula in a manner similar to that employed to decide the various events at the recent Algonquin hill climb, run by the Chicago Automobile Club. This arithmetic-involving calculation calls for the following rule: Cylinder capacity of the car multiplied by the time in seconds, divided by the weight of the car with driver. When this result is obtained, the contestant having the lowest percentage is the winner. The vagaries of this formula are amusing, as results of the Algonquin climb showed that in some cases the lightest car in a class had the advantage, while in others, the heaviest in the group did better than the light-weights.

Zust Drivers Catch a Trolley Tartar.

The Zust competitor in the New York-Paris race is still doggedly fighting out the battle in a "Paris or bust" spirit and during a stop last week at Kazan, a city located somewhere within the bounds of the Russian Empire, the drivers indulged in a glorious trolley ride for a change. Scarfoglio, the "war correspondent" on the Zust car, wired from Kazan as follows:

"The treacherous sun has forsaken us. For the last four days the sky has been shedding all its tears upon the Zust car and its crew. The Russian roads are bad enough normally, but this persistene rain has made them worse than ever.

"Nevertheless we feel we are nearing Paris, our goal, and so speed on day and night. We arrived here at dawn today, and intend to start again at noon. Barring accidents we shall reach Nijni Novgorod tomorrow night, Moscow the day after, and St. Petersburg soon afterward.

"While the mechanics were rapidly overhauling our motor we gave ourselves up just now to the glorious delights of a ride in an electric tramway car. In our enthusiasm we wished to embrace the conductor, but he was a Tartar.

Evidently the Zust drivers do not relish Tartar sauce between meals.

Doing One Hundred Double Centuries.

Two hundred miles a day for 100 days is the tall order that a Chalmers-Detroit "30" has undertaken to fill, and already it has delivered two weeks of it. Four times a day the machine makes the round trip from Detroit to Pontiac, Mich., and as the cities are 26 miles apart, the two morning and two afternoon journeys total over 204 miles. After 2,800 miles the car gives every evidence of completing its 100 days in a fashion that will prove its capacity for road service.

Race Meet for the Twin Cities.

Enthusiasts among the members of the Minneapolis (Minn.) Automobile Club are hungry for some motor racing and have secured a sanction from the A. A. A. to hold a race meet on Saturday, September 5. Several entries for the card have been assured and the club expects the local gasolene lovers to turn out in quite a mob. The following races have been scheduled: One mile, free-for-all time trials; five miles, gasolene stock chassis, 60 horsepower and under; 5 miles, Twin City championship for fully equipped stock cars; 5 miles, free-for-all, best two out of three heats, not more than two cars to compete in a heat; 25 miles, gasolene stock chassis, 60 horsepower and under; 5 miles, open to gasolene cars selling under $1,250.

Louisville Selects a Race Date.

Advices from Kentucky state that the Louisville Automobile Club has definitely decided to hold its race meet in that city on September 12 and that George Salzman, with a six-cylinder Thomas will be the drawing card of the affair. The club is endeavoring to promote the sport in Louisville and some of the foremost citizens are on its racing committee and are assisting the movement.

FAVORS ELECTRIC OMNIBUSES

Discussing the Situation in London, Bernard Hopps Concludes Storage Batteries Offer Best Solution.

Motor omnibusses and their operation have proved a fruitful topic of discussion for British engineers during the past year or two, owing to the peculiar combination of circumstances which have governed the performance of these machines on the streets of London. The latest contribution to a long series of technical papers on the subject is by Bernard Hopps and was delivered before the Rugby Engineers' Society. After reviewing the causes which led up to a number of financial disasters in this line following a year or two of apparently successful operation, the author announces that present conditions are such as to offer inducements to promoters to introduce still other companies into the public motor vehicle service.

"There are today over 900 motor 'buses in London, 85 per cent. of which are owned by the three principal companies," he remarks. "Many of the 'bus companies in London are at present handicapped with a fleet of more or less obsolete vehicles, which they cannot sacrifice owing to the enormous capital expenditure they represent, and yet which cannot be run at a profit owing to the heavy maintenance charges. How long this condition of affairs will last it is difficult to say. The present vehicles cannot run for more than a few years before they will be reduced to scrap value, but in the meantime these companies are apparently not in a position to consider the purchase of new vehicles.

"There seems to be, therefore, at the moment, an opening for new 'bus companies in London, who would have for their guidance the valuable experience that the older concerns have bought so dearly. They would not be handicapped with obsolete vehicles, but, on the contrary, would have the advantage of acquiring up-to-date machines, specially constructed to meet the service conditions in London, and designed from the experience that has been gained. By the employment of only one type of vehicle the running cost would be materially reduced and the whole system of maintenance could be greatly simplified.

"The question arises what is the most satisfactory type of vehicle for service conditions as obtain in London? The available systems may be summarized as follows: Steam; petrol engine with mechanical change-gear, with hydraulic transmission, or with electric transmission; and electric drive with accumulators.

"Of the above systems two have been extensively tried in London service, i. e., steam, and the petrol engine with mechanical change-speed gear. . . . For net loads of five tons and upwards, it is generally admitted that steam is the more satisfactory; on the other hand, for loads of two tons and less, the petrol engine has the advantage. For vehicles carrying loads between the limits of two and five tons, in which category may be classed omnibusses, the relative advantages of the two systems is a debatable subject.

"As regards the petrol-hydraulic system, several schemes have been proposed, some of which have been tested, but, as far as the author is aware, this system has not been subjected to a prolonged service trial on a London motor 'bus, and therefore little can be said of its practicability for that class of work.

"With the petrol-electric system it is proposed to deal in greater detail, as here more information is available. During the past few years considerable attention has been paid to this form of transmission, and several systems have been placed on the market. In studying these it must be remembered that the first aim in designing a 'bus for London service should be to reduce everything down to the simplest possible form. The electrical equipment must be self-contained and sturdily built. It must be so simple that it can be taken to pieces and re-erected satisfactorily by an ordinary fitter, who has no electrical training, for it must be borne in mind that the average motor 'bus mechanic is necessarily more skilled in matters pertaining to the petrol engine than to electrical machinery.

"Petrol-electric systems may be roughly grouped under the following headings: (a) Those which start and accelerate electrically, after which the electric drive is cut out and is taken up by a clutch driving direct through from engine. (b) Those which employ accumulators to assist the engine in climbing grades. (c) Those which drive entirely electrically.

"It is claimed for the first method (a) that since the electrical equipment is only used for starting and accelerating, it can be made comparatively smaller, lighter and cheaper. This is an erroneous idea, as it is not practicable to limit the output of the electrical equipment to starting and acceleration duties only, since occasion will arise where hills of considerable length must be negotiated, the gradient of which will be too severe for the direct drive, and which, therefore, must be climbed entirely through the electrical transmission. Since such grades represent the most severe duty for the electrical equipment, it follows that in order to avoid over-heating, it must be made just as large and heavy as would be necessary were it called upon to propel the vehicle during the whole of the working period.

"It may be said that for service in our large cities, as, for example, London, the grades encountered are insignificant and can be surmounted with the direct drive, but for this class of service where traffic is always congested, and where constant stops and starts are necesary, there is no real advantage in employing a direct drive to decrease the duty of the electrical equipment, since it cannot be used for sufficient length of time.

"It is further claimed for this system that the so-called direct drive at full speed is more efficient than a purely electrical transmission. Assuming that this is so, and that a few per cent. saving in efficiency may be obtained owing to the elimination of the electrical losses, which at full speed, however, are at their minimum, this arrangement introduces a clutch, which complicates the mechanism and adds another item of upkeep. It also necessitates the alignment of the motor, generator and engine. It limits the speed of the motor to that of the engine, whereas with a purely electrical drive, the motor can safely be run at double the speed of the engine with a corresponding saving in weight and cost.

"With regard to the second system (b) in which accumulators are used to assist the engine, it is somewhat difficult to see what advantage is obtained by their introduction; they add a complication, and require a special organization to attend to them. The accumulator usually employed is the Planté type, which it is true will withstand a considerable amount of abuse both as regards heavy discharges and vibration, but the battery required is as heavy, and as costly as an electric motor would be, and far more expensive in upkeep. The simplicity of the control is sacrificed, and a skilful driver is essential to operate such a system efficiently. For heavy country service in which steep hills have to be negotiated, the discharge rate on the accumulators is high, and there is the possibility that they may become totally discharged before the top of the hill is reached. The only advantage that can be claimed for such a system is that of recuperation during the braking and coasting periods.

"There remains the third system (c), the pioneers of which in this country were the British Thomson-Houston Co. This consists of a direct-current dynamo driven by a petrol engine, the whole of the engine power being converted into electrical energy, which is transmitted through a controller to the motor or motors driving the road wheels.

"In this system, either one or two series-wound motors may be used, depending on the nature of the service. For vehicles in London, the single motor with a single commutator is to be preferred, on account of reduced weight, cost, and simplification of the controller, although it necessitates the retention of the differential gear; for hilly country work, the double motor equipment, or its equivalent, is essential.

"The chief feature of this system is the constant watt output auto-regulating dynamo, which reduces the control to its simplest form, and thus renders the employment of skilled drivers unnecessary.

"In order to fully appreciate the advan-

Digitized by Google

tages of this machine it is necessary to study the characteristic of the petrol engine that drives it. The maximum horsepower that can be developed by a petrol engine is limited to practically its normal working output. The torque developed remains approximately constant; it follows, therefore, that as the speed diminishes, due to overload, the horsepower developed diminishes, and this at the time when the maximum brake horsepower output is most required. In this respect it is unlike a steam engine, which can be made to develop considerably more than its normal torque for short periods by increasing the cutoff and the steam pressure.

"In the case of a gear-driven 'bus of the usual type, in order to provide sufficient torque at starting, it is necessary to introduce a comparatively large gear-ratio between the engine and the road wheels. It is small wonder the drivers become fatigued and careless at the end of a day's work, during which the gears are changed on an average of some 800 times in London service.

"The use of the auto-regulating dynamo eliminates the whole of this work and consequent fatigue, and its action may be described as follows:

"At starting, the motors demand a large current in order to develop the necessary starting torque; the dynamo supplies this current, but at a very low voltage. As the motors speed up they automatically demand less current, which is supplied by the generator, but at an increased voltage. In other words, the voltage of the generator varies in inverse ratio to the ampere output, therefore the power required to drive it can never exceed a certain predetermined maximum, which is arranged to correspond to the maximum power of the engine. Whatever the current demand may be from the generator, it cannot cause an overload on the engine sufficient to reduce its speed and horsepower output.

"Almost as important a feature in this system as the generator is the system of control, which has been reduced to the simplest possible form. In order to stop the vehicle the current is not interrupted at the main controller, but the voltage of the generator is reduced to zero by inserting a high resistance in the generator field, and at the same time reducing the engine speed. This is accomplished in practice by a single pedal. On releasing the pedal the first movement cuts out the resistance, and the generator volts build up on the load, causing sufficient current to flow to the motors to start the vehicle, which will continue to run slowly, the engine remaining governed at 400 revolutions per minute. On entirely releasing the pedal the governor is 'held up,' allowing the engine speed to at once increase to its normal value and the vehicle to smoothly and rapidly accelerate to its full speed. To slow in traffic it is merely necessary to more or less depress the pedal, thereby reducing the engine speed, and consequently the generator voltage and the vehicle speed.

". . . . In view of the favorable costs for running petrol gear driven 'buses that were quoted by leading authorities a few years ago, accumulator traction for this class of work was regarded as commercially impossible. Experience has shown that these costs were placed too low, and that the petrol 'bus costs at least 25 per cent. more to maintain than was at first anticipated. The 'bus companies admit the present vehicles give an enormous amount of trouble to maintain, and that the cost of maintenance is a variable one, depending largely on the driver. Skilled mechanics will not undertake the duties of a 'bus driver, and the men who are employed are usually at a loss to rectify small derangements of the engine, etc., which often occur on the road, and therefore it is necessary to employ a staff of road adjusters, who are stationed along the routes to render skilled assistance in cases of breakdowns.

"In the light of the experience gained with the petrol gear-driven 'bus, the prospects of accumulator traction are much brighter. The accumulators themselves have been improved in detail, and accumulator manufacturers are now prepared to enter into contracts to maintain the accumulators at a flat rate per car mile, which at once relieves the operating companies of all anxiety as to the cost of their upkeep."

Young Thief Emulates the Flea.

Writers of dime novels have justification for the exploits recorded in their "thrillers" in the bold career of Ernest Diebler, a Chicago youth, who after being arrested for stealing a $3,000 touring car from the Haynes Automobile Co.'s Chicago store, escaped from the officers of the law and stole the same machine over again, this time from the police who guarded it and in whose custody it was held. After a long chase he was captured the second time but escaped once more by jumping through the window of the railway car in which he was being taken from Seattle back to Chicago The girl for whom he is said to have stolen the machine lives in Portland, Ore., and a close watch was kept for him in that city. The youth finally turned up and was again arrested, but he told such a plausible story about being E. W. Smith and not the man sought that he was released. Telegraphic urgings from Chicago to hold him for identification were received shortly after, however, and before he could leave the city he was taken to jail once more. How many times he will escape and steal the automobile remains to be seen.

Oil-Soaked Pavement Causes a Fire.

"Burning up the road" has a new significance in Chicago, following the exciting incidents of a pavement fire which this week scorched several automobiles and gave the women passengers the scare of their lives. At Clarke and Monroe streets, where many machines were lined up in front of Rector's restaurant, the gasolene and oil drippings of the season had saturated the wooden paving blocks to a point where they only needed a flame to ignite, and this was supplied by a smoker who after lighting his evening cigar tossed the burning match into the gutter. Instantly there was a flare which illuminated the whole street and the fire swept the road surface in leaps. It licked the varnished tonneaus and frizzled the tires of the cars along the curb, and precipitated a general scramble on the part of the passengers to get out and the chauffeurs to move their charges away from the flames. Patrons of the cafes and restaurants ran out and added to the tumult, while the fire department came at a gallop. Because of the floating oil and gasolene, water was not used and the fire was smothered out with pails of sand and the spreading of tarpaulins. No explosions or serious damage took place, but the conflagration points to a very plain lesson for garage owners in particular.

Possible Markets for American Cars.

According to Consul James Johnston, of Algiers, there are good prospects of a permanent market in Algeria for a light, strong, moderate-priced car. Automobiles are extensively used by wine and oil merchants who have to travel in districts where as yet the railway does not exist.

In order to introduce American motor cars and establish a market therefor the manufacturer must be prepared for a little expense, he says. The only effort that appears to have been made thus far in this direction has been to send catalogues in English, but it is unreasonable to expect to sell motor cars on the strength of catalogue descriptions, and no agent would entertain the idea of representing a line of automobiles unless he had a sample car for demonstration.

The duty on motor cars from the United States is 60 francs per 100 kilograms ($115.80 per ton of 2,240 pounds) on cars weighing 125 kilos and over. The duty on the same cars from other countries is 50 francs per 100 kilos ($96.50 per ton).

American Consul R. M. Bartleman, of Madrid, writes that there are over 700 automobiles in the Spanish capital, and a good market for more, including American machines, if they can compete with those now on sale. No American cars are now on the market.

Motor Cabs and Buses in London.

Consul-General Robert J. Wynne reports that a statement by the home secretary shows that there is now one motor-omnibus for every two horse omnibuses plying in the streets of London. The full statement of the number of licensed vehicles in London is as follows: Taxicabs 1,508, hansoms 5,329, four-wheeled cabs 3,768, motor omnibuses 1,046, horse-drawn omnibuses 2,281; total, 13,932.

The Week's Patents.

889,267. Four-Cycle Motor. Alexander G. Spencer, Rahway, N. J. Filed June 28, 1906. Serial No. 323,953.

A four-cycle motor comprising a cylinder having in its side an exhaust port and at its head end an inlet for the combustion motive fluid and an inlet valve therefor, said end of the cylinder being permanently closed except for said inlet, a piston within said cylinder, a piston rod pivotally connected with said rod, said exhaust port and piston being in proper relation to each other to enable said piston to cover said port during nearly the whole of the suction and power strokes of the same and to uncover said port at about the end of the suction and power strokes of said piston, whereby on the suction strokes of the piston the said fluid is thereby drawn into said cylinder and on the conclusion of the power strokes thereof the products of combustion discharged wholly through said exhaust port then uncovered by said piston; substantially as set forth.

889,310. Drive Attachment for Vehicle Wheels. Joseph H. Joaquin, St. Louis, Mo. Filed May 14, 1907. Serial No. 373,688.

1. A device of the class described, comprising a cap, a flange formed integral with said cap, said cap placed over one-half of the hub and retained in position to the spokes of the vehicle by means of said flange, a second flange formed integral with the cap, an externally screw threaded shoulder formed on the cap, and a sprocket wheel removably attached to the cap, substantially as specified.

889,338. Igniter. George J. Schultz, New York, N. Y., assignor to Benjamin Briscoe, Tarrytown, N. Y. Filed Feb. 26, 1907. Serial No. 359,422.

1. In an ignition device, the combination with a shell having a central opening and carrying a plurality of sparking points, a body of insulating material located within the opening of said shell, but being of less area than said opening, sparking points carried by said insulating material for co-operation with the sparking points carried by the shell, said body of insulating material carrying a translucent flange of insulating material, and means for securing said flange to said shell.

889,362. Speed Changing Mechanism. Walter O. Foss, Philadelphia, Pa., assignor of four-fifths to George Link, Frederick C. Brunhouse, Philip G. Lang, and Ralph E. Brunhouse, Philadelphia, Pa. Filed Jan. 21, 1908. Serial No. 411,947.

1. A power shaft, an axle, a plurality of interchangeable power transmission mechanisms slidably mounted upon said axle, each mechanism consisting of a driving disc, bevel gear and clutch, and a clutch on said power shaft adapted to engage either of the clutches of said power transmission mechanisms, substantially as described.

889,402. Carriage and Automobile Body. Maurice J. Rothschild, New York, N. Y., assignor to Rothschild & Company, New York, N. Y., a Corporation of New York. Filed Sept. 16, 1907. Serial No. 393,001.

1. The combination with a frame or support, of a body covering or sheeting therefor, and a bar conforming to the shape of said frame and secured to said covering by permanent flexion of the edge of the latter.

889,432. Spark Plug. George J. Blum, Chicago, Ill., assignor to Armstrong-Blum Manufacturing Company, Chicago Ill., a Corporation of Illinois. Filed Feb. 7, 1906. Serial No. 299,933.

1. In a spark plug, in combination, an electromagnet; a fixed contact; a movable contact; a finger for carrying said movable contact; a sectional shaft between the sections of which said finger is clamped; and an armature clamped to said shaft.

889,450. Timing Device for Jump Spark Ignition Systems. William D. Foreman, Chicago, Ill. Filed July 5, 1907. Serial No. 382,226.

1. In a timing device of the character described, the combination with a rotary member and an adjustable stationary member provided with electrical contact pieces, of a brush carried by said rotary member, and a contact cleaner slidably supported on said rotary member to be movable relative thereto.

889,487. Carburetter for Internal Combustion Engines. Joseph C. Schneble, Dayton, Ohio, assignor of one-half to Theodore C. Schneble, Dayton, Ohio. Filed May 28, 1907. Serial No. 376,100.

1. In a carburetter, the combination with a cylindrical air chamber and a fuel nozzle located axially therein, of an annular air valve provided with a skirt from its central opening surrounding the fuel nozzle when the air valve is closed, a central needle valve controlling the opening in the nozzle, and rotating cams for operating the air valve and the fuel valve, simultaneously, substantially as set forth.

889,437. Power Drum Gearing. Charles F. Callahan, Pasadena, Cal. Filed Jan. 16, 1908. Serial No. 411,171.

1. In combination with the propeller shaft, a drum mounted transversely thereof, a gear at one end of the drum, a sleeve slidable on the propeller shaft, a pair of bevel gears on said sleeve, a yoke pivotally supported on the propeller shaft, a shaft journaled in said yoke, a gear on the latter shaft adapted to be engaged by either of said first named bevel gears, another shaft connected by a universal joint with the latter shaft, a rotating sleeve in which the last named shaft is slidably mounted, and a spur gear on said rotating sleeve meshing with the gear on said drum.

889,489. Shock Absorber for Vehicle Wheels. William E. Snediker, New York, N. Y. Filed March 16, 1907. Serial No. 362,670.

1. A shock absorber for vehicle wheels comprising a resilient cushion interposed between the main axle and its wheel, a stub axle bearing the wheel and a lever movable with reference to the stub axle and main axle and reacting against the resilient cushion.

889,528. Speed Controlling Mechanism for Automobiles. Thomas B. Jeffery, Kenosha, Wis. Filed Jan. 12, 1907. Serial No. 351,934.

1. In a motor driven vehicle, a motor for propelling the vehicle at various speeds, a motor controller, a speed indicator driven in time relation with said motor so as to show the speed at which the vehicle is traveling, operative connections between said controller and said indicator for causing the controller to be actuated upon variations in the speed, said indicator including relatively movable co-operative dial and index members located within reach of an occupant of the vehicle, and said latter members being so arranged that relative movements may be effected between them by such occupant.

WANTS AND FOR SALE.

15 cents per line of seven words, cash with order. In capitals, 25 cents per line.

FOR SALE—300 sets 28x3 best grade artillery wheels, fitted with clincher rims, less hubs. Write for bargain prices on single sets of the lot. THOMAS B. JEFFERY & COMPANY, Kenosha, Wis.

The new Sealed Can protects you against substitution—always see that the seal is not broken. Write for our free booklet on lubrication, and let us recommend the proper grade of Panhard Oil to suit your type of motor.
GEO. A. HAWS, 84 Pine Street New York City

889,158. Carburettor. Horace T. Thomas, Lansing, Mich., assignor to Reo Car Co., Lansing, Mich., a Corporation of Michigan. Filed No. 13, 1905. Serial No. 286,993.

1. The combination with a casing of an air and a constant level float chamber formed therein, a hollow valve projecting within the air chamber and provided in its inner end with an air inlet port in constant open communication therewith and in its outer end with a discharge port communicating with an outlet from the casing under control of the valve, a seat for the valve provided with an opening, a hydrocarbon supply nozzle concentrically arranged in said opening, and means for rotatorially adjusting the valve, said valve adapted to be registered with the opening in the seat of the valve.

889,585. Tire Case. Lewis G. Cook, Detroit, Mich. Filed May 24, 1907. Serial No. 375,494.

1. In combination with the circular concaved body part of a receptacle, a half cir-

Digitized by Google

cular concaved cover part hinged to said body part and provided with staples near its ends, a second half circular concaved cover part hinged to said body part and provided with holes adapted to engage over said staples, bolt members carried by said staples and adapted to be retracted within the walls thereof, a spring for projecting said bolt members and thumb latches for retracting said bolt members, substantially as described.

889,678. Shock Absorber for Self Propelled Vehicles. Charles B. Hatfield, Cortland, N. Y., assignor to Hatfield Motor Vehicle Company, Cortland, N. Y., a Corporation of New York. Filed Nov. 23, 1906. Serial No. 344,729.

1. In combination with the body and running gear of a vehicle, a motor on the body, an endless belt for transmitting motion from the motor to one of the traction wheels, a rock-arm pivoted near the axis of the wheel, a roller on the rock arm receiving and guiding the belt, and means for rocking said arm to press the roller against the belt with sufficient force to deflect a portion thereof from a direct line to resist upward thrust or rebound of the body of the vehicle.

890,533. Speed Regulating Device. Alfred P. Schmucker, Denver, Colo. Filed Jan. 8, 1907. Serial No. 351,329.

1. In speed regulating mechanism, the combination of a liquid containing reservoir, a driving shaft, a driven shaft, means located in the reservoir for circulating the liquid therein as the driving shaft is rotated, the said means including two co-operating members, one of which is eccentrically mounted in the other, and slidable means surrounding the outer member and independent of the shafts for controlling the exit port, whereby the passage of liquid therethrough may be cut off to any degree desired, for the purpose of regulating the speed of the driven shaft as compared with that of the driving shaft, substantially as described.

890,565. Change Speed and Reversing Gear. Charles B. King, Detroit, Mich., assignor to Northern Motor Car Company, Detroit, Mich., a Corporation of Michigan. Filed April 3, 1905. Serial No. 253,585.

1. The combination of a change speed mechanism having adjustable connections to secure different speed ratios and an adjustable connection to secure reverse motion, a rod adapted to slide longitudinally to shift the connections to secure different speed ratios and to rotate to actuate the adjustable connection to secure the reverse action, a second rod secured to the first rod so as to be free to change its position laterally, but restrained from rotation relative to the first mentioned rod, means for shifting the second rod laterally and longitudinally, said second rod being provided with a laterally extending arm, and means for restraining the motion of the outer end of said arm laterally to said rod whereby said rods are turned about their axis.

889,679. Self Propelled Vehicle. Charles B. Hatfield, Cortland, N. Y., assignor to Hatfield Motor Vehicle Company, Cortland, N. Y., a Corporation of New York. Filed Jan. 26, 1907. Serial No. 354,308.

In a self-propelled vehicle, a body and a running gear having a traction wheel, a liquid hydro-carbon engine mounted on the body of the vehicle and provided with opposed cylinders arranged transversely of the body, said engine having a crank shaft extending lengthwise of the body, a friction disc secured directly to the crank shaft and provided with a central floating rest concentric with its axis, the friction face of the floating rest being coincident with the remaining portion of the friction face of the driving disc, a shaft mounted transversely on the body parallel with the friction face of the driving disc, a second friction disc rotating with the shaft in permanent contact with the friction face of the driving disc and movable axially, means for moving said second disc axially in a diametric line across the face of the driving disc, and means for transmitting motion from the shaft to the traction wheel.

889,769. Change Speed Gearing. Jules L. Didier, St. Cloud, France. Filed Jan. 28, 1907. Serial No. 354,527.

1. A change speed gearing comprising driving and driven elements, motion transmitting devices operatively connected to the respective elements, and a pair of relatively movable plates arranged to frictionally engage the motion transmitting devices between them and form a direct driving connection between said elements.

889,782. Spring Wheel. Sylvester W. Higgins, Detroit, Mich., assignor of one-half to Frank H. Farnsworth, Detroit, Mich. Filed May 31, 1907. Serial No. 376,491.

1. A vehicle wheel comprising a hub, a rim normally concentric with the hub, having inturned marginal flanges, a plurality of closed spring metal loops interposed between the hub and rim, in close-pressed contact with each other and the hub and rim, and a pair of parallel flanges adjustably secured on the hub on each side of the springs adapted to frictionally engage the edges of the springs for a major portion of their extent.

889,839. Self Propelled Vehicle. John Wilkinson, Syracuse, N. Y., assignor to H. H. Franklin Manufacturing Company, Syracuse, N. Y., a Corporation of New York. Filed March 11, 1904. Serial No. 197,664.

1. In a vehicle, the combination of the running gear, an internal combustion engine provided with a plurality of air cooled cylinders and with pistons movable therein, and a crank shaft common to all of the cylinders, the cylinders being arranged side by side lengthwise of said shaft and in substantially upright planes at the front of the running gear, and each being provided with external radiating projections, and power transmitting means connecting the running gear and the engine for propelling the vehicle substantially as and for the purpose described.

889,886. Starting Mechanism for Gas Engines. William K. Andrew, Milwaukee, Wis., assignor to International Harvester Company, a Corporation of New Jersey. Filed Dec. 11, 1907. Serial No. 405,981.

1. A starting mechanism for gas engines comprising, in combination, a cam shaft, a rotary valve connected with said cam shaft in a manner to be rotated therewith, a valve casing having said valve mounted therein, said casing having inlet and outlet ports communicating with a source of compressed air supply and an engine cylinder, respectively, and inlet and outlet exhaust ports communicating with the engine cylinder and atmosphere, respectively, said rotary valve having a channel that communicates with said air and exhaust ports alternately.

889,889. Power Transmission Device. Joseph E. Barrett, Detroit, Mich., assignor of one-third to Harry J. Ferrell and one-third to John H. Connor, Detroit, Mich. Filed Aug. 28, 1907. Serial No. 390,483.

1. In an automobile, a motor, a drive shaft, a friction disc, a coupling on the drive shaft having a part movable longitudinally on said shaft, a universal joint between the motor and drive shaft, means for sliding the movable part of said coupling a driven shaft, a slidable friction wheel on the driven shaft, and means for shifting said friction wheel with relation to said friction disc.

889,897. Mechanism for Operating Variable Ratio Gearing. Swinfen Bramley-Moore, London, England. Filed Dec. 8, 1906. Serial No. 346,928.

1. Mechanism for operating the velocity ratio gearing of motor road vehicles comprising two bars pivoted so as to swing in the same plane, extensions of said bars sliding in fixed relation to the said bars, a pivoted operating lever engaging the free ends of the said extensions, and a slotted plate adapted to act as a guide for the operating lever as set forth.

889,927. Automobile Tire Casing. Charles L. Higgins, Montreal, Quebec, Canada. Filed April 6, 1906. Serial No. 310,337.

1. In the manufacture of coverings for tire casings and the like, cementing a strip of leather with its side edges skived to a layer of "frictioned stock," cementing a pair of narrow strips of "frictioned stock" along such skived edges, coating the exposed surfaces of "frictioned stock" with uncured rubber, and finally vulcanizing the whole.

889,951. Shock Shifter Hub. John Muir, Beith, Scotland. Filed April 27, 1906. Serial No. 313,965.

1. The improved mechanism for absorbing shocks transmitted from the periphery of a wheel, to its center, consisting of a ball chamber surrounding the central hub and containing a number of balls, rollers or other rotatable elements superimposed in layers upon one another and having a free space within the chamber; said rotatable elements so superimposed as to receive and distribute the shocks by slipping over one another, substantially as described.

WILL BE ON MOST CARS IN 1909—WHY? ASK THOSE WHO HAVE TESTED IT

Digitized by Google

Mongrel or Thoroughbred?

NOW IS THE TIME for you, Mr. Thoughtful Dealer, to decide what you will sell in 1909.

WILL IT BE A MONGREL? a car assembled from parts carried together from all over the country and hammered into shape as well as may be?

OR WILL YOU SELL THE THOROUGHBRED—a homogeneous mechanical masterpiece, every single part of which is the result of the same genius that devised the whole?

"ASTOUNDING," "MARVELOUS," "WONDERFUL," are the terms with which some assembled cars are now tagged, though they are astounding, marvelous and wonderful only to the assemblers, who like Rip Van Winkle, have been dozing in the growing woods of automobiledom and who now, bewildered by the progress that has been going on, seize upon time-tried and long-established practices and herald their adoption by the assemblers as brand-new discoveries.

LET'S REASON IT OUT: On the one hand you have the assembled car, with an engine bought from one manufacturer, a frame from another, and a transmission from a third, and so on down to the last rivet. The maker of the engine, the mill in which the frames are pressed, the transmission man, all derive their separate profits, leaving no other way to the assemblers to obtain their rewards than by skimping the quality of their "product."

AND THEY DO IT—THEY MUST! When you examine some of these astounding cars you will be truly astounded on finding that the four-cylinder engine is cast in one piece and has only two main bearings, whereas the Maxwell has four cylinders and five main bearings. You know well enough that making a motor with only two bearings is equal to leaving the engine to its own devices as far as alignment is concerned.

IT WILL BE A TOUGH JOB FOR THE DEALER to convince the purchaser who is wise that some four-cylinder engines of small dimensions will develop as high as 30 horsepower—because they can't.

MAXWELLS ARE A HOME-GROWN AMERICAN PRODUCT. The use of Maxwell features in Maxwell cars was neither a heaven-given inspiration nor the aping of foreign design, but the outcome of sound engineering sense.

WHEN 10,116 MAXWELL OWNERS testify to the excellence of their cars, all of which have been sold by Maxwell dealers, then the Maxwell proposition is one that you can't afford to pass by.

BEFORE HITCHING YOUR WAGON TO A STAR it will be wise for you to find out all about a dealership for Maxwells, the success of which is past and present, instead of lying in the dark and distant future that has swallowed so many wonderful cars that have been marvelous chiefly in their complete and rapid disappearance from the field of legitimate competition.

Benj. Briscoe

President.

Perfection in part will produce perfection in the whole

"Firestone" TIRES

"The Tires of Sterling Quality"

are constructed on this principle.

Ever keeping in mind the sole aim—the raising of the standard of pneumatic tires—we employ the most expert tire builders in the various courses of construction.

Each expert forwards his product on the basis of the best that he can do—he has already made his record—he cannot go back of that—he must do as much better as he can.

All the perfected parts are assembled with method and deliberation—making the perfected whole—the best tire made.

Branches and Agencies Almost Everywhere.

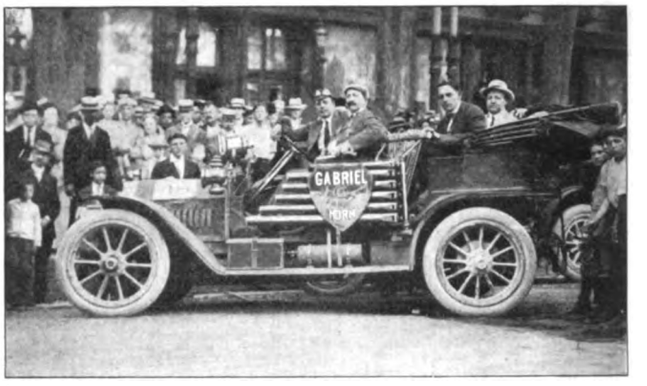
"Solar Lamps Invaluable!"

Says Schuster, Driver of Thomas Car, New York-Paris Race.



BADGER BRASS MFG. CO. August 18, 1908.

Gentlemen: It may interest you to know that from the time we left New York until we reached Paris our Solar Lamps gave absolute satisfaction, in fact, they were invaluable! Meeting the worst possible road and weather conditions both in America and Siberia, they did their work in the most satisfactory manner and at no time did they give us any trouble. I consider them to be the best automobile lamp made.

Yours truly, George Schuster

BADGER BRASS MANUFACTURING CO. 606 Lyman Avenue KENOSHA, WIS.

A Successful Test

The cut illustrates the Gabriel Horn car which accompanied the Glidden Tourists; a trip made to test the Gabriel Horn and Gabriel Shock Absorbers. Over all roads, rough and even, both gave extreme satisfaction and demonstrated that they are the best on the market to-day.

THE GABRIEL HORN can be attached to exhaust of any car, steam or gasoline.

THE GABRIEL SHOCK ABSORBERS for any car or any spring; make easy riding and protect both the springs and occupants of car.

THE GABRIEL CUT-OUT VALVE relieves back pressure of engine and assists in speeding, hill climbing and on heavy roads. Write for prices to-day.

GABRIEL HORN MFG. CO.

1417 E. 40th St., CLEVELAND, O.

WEED

Something for a rainy day

Just when it starts to rain—when the first drop falls—put on your

WEED CHAINS

Don't take chances! With Weeds on your tires you can negotiate on slippery asphalt or muddy roads without any chance of skidding. Your road wheels will not spin and waste your gasolene. Fit any standard tires, are readily attached and detached.

WARNING TO THE TRADE; This company owns and controls all patents upon "Chain Anti-Skidding Devices," (whether secured permanently on the tread or loose so as to "creep" or move freely during rotation of wheel). Suits against unscrupulous manufacturers for infringement of patents are now pending. The Trade is warned not to buy or sell any WEED imitations.

Write for "THE WEED," an interesing Bulletin on the automobile subject.

Weed Chain Tire Grip Co.

on a midwinter trip from New York to New Orleans, Mr. Ralph Owen driving an **Oldsmobile,** found in plenty, incidents and conditions of the sort that showed the kind of stuff men and things are made of.

When you stop to consider what an automobile is built and intended for, the endurance of this car is marvelous. He says:

"Between Blue Stores and Hudson the road was particularly rough and rutty, and as we were nearing Hudson one of our rear tires was wrenched off in a frozen rut which was nearly eight inches deep. At Buffalo, a thorough examination of the car was made to see if the terrible strain under which it had been the last three days had in any way decreased its efficiency, but aside from a broken spark plug, which had given us some annoyance the last ten miles into Buffalo, nothing was discovered."

This Car was equipped with TIMKEN ROLLER BEARINGS AND AXLES

Has it ever occurred to you WHY the manufacturers invariably equip the cars they pick for such trips, with **Timken Product?** There is a reason. May we give it to you?

THE TIMKEN ROLLER BEARING AXLE COMPANY, Canton, Ohio

Branches: 10 E. 31st Street, New York. 429 Wabash Avenue, Chicago.

THE BRAMPTON MOTOR CHAIN

All side plates on both sides of the Brampton Chain are stamped **"BRAMPTON."**

LARGE SALES and SMALL PROFIT with thousands of satisfied customers is our best advertisement. THE BRAMPTON CHAIN is made of self-hardening Steel; the strongest Chain in the World. All parts polished; fits sprockets (that are properly cut) without friction.

Some of the other chains may look like **THE CELEBRATED BRAMPTON CHAIN** because some of the other chain makers began to copy the design and shape of the **BRAMPTON CHAIN** links in 1904. They have improved somewhat on their copied design from time to time until these chains now look more like the **BRAMPTON CHAIN** than ever before. These chains somewhat resemble the **BRAMPTON** in appearance, but the manufacturers of such chains have been unable to copy the material —self-hardening steel.

NO CHANGE IN THE BRAMPTON

There has been no change in the design, construction, material or finish of the **BRAMPTON MOTOR CHAIN** in the past ten years.—**"ENUF SED."**

PRICE

The price being equal, it's presumable you want the best, and full value for your money. In such cases, the **BRAMPTON FILLS THE BILL,** and the prices are the same to manufacturers, jobbers, dealers and consumers as any other chain of equal size. We have in stock chains to fit all American and foreign cars.

YOUR 1909 CAR

You can have the new car that you order fitted with the **CELEBRATED BRAMPTON CHAIN** if you order it that way. No **extra** cost to either you or the manufacturer. All standard sizes in stock to fit American and Foreign Cars at the same price as the other chains.

SPECIAL CHAINS TO FIT THE INDIAN MOTORCYCLE.
Agents wanted in unoccupied territory. Catalog on request.

The Mitchell

The car you can afford to buy and KEEP

$2000

The Mitchell appeals **to you,** Mr. Business Man, because it gives you just as much **pleasure**—just as much and as **good service,** is just as **stylish** and neatly **finished** as any car, and doesn't cost you a small fortune to **buy**—or **keep.**

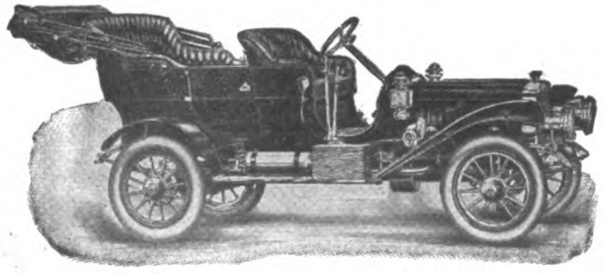
The Mitchell at $2,000 is the standard automobile value.

Prove it—Mr. Business Man.

Get **demonstrations** of the extravagantly high-priced cars—and then try the **Mitchell** over the **same** route.

The Mitchell agent will be glad to take you out if you're interested for 50 or 100 miles any time you say. Call him up (it places you under no obligation)—**Challenge** him—

Just say, "Show Me."



He'll come around with a car and show you a "silent argument" that will get your order or he will retire without a word.

Our catalog No. 18 is fully descriptive of the Mitchell 1908 Touring Car $2,000—Limousine $2,800—Roadster $1,250, and Runabout $1,000. Write for it—we'll also send letters from users, proving the Mitchell to be the most economical car to **operate.**

Mitchell Motor Car Co., 285 Mitchell Street, Racine, Wis.

Standard Manufacturers, A. M. C. M. A.

This car—shown here—35 h. p., 4 cyl., speed 50 miles, finished in Mitchell blue—price $2000—is excellent throughout—the car you ought to have at the price you ought to pay.

Warner Auto-Meter

GUARANTEED FOR ONE YEAR.

"Thirty Days' Free Trial"

When a manufacturer is willing to send his product to anyone, anywhere, for 30 days—with no deposit, no agreement to buy, no promise to do anything except give that product a fair trial—he must have more than ordinary confidence in his article. In order for him to have that confidence he must have a most extraordinary product.

That's what we do. We'll send an Auto-Meter to any automobile owner in the country—with no deposit, no agreement, no promise to do anything but put it on his car and give it a fair trial. It doesn't matter whether he has another make of speed indicator already on the car or not. Indeed, for the sake of comparison, we hope he has. We will abide by the decision—for he will always keep the indicator that tells the truth. We claim for the Auto-Meter that it is the only one of which "the dial never lies." We believe that the instrument itself is the most eloquent salesman we have—we're willing to let it do our talking. Send to-day—just tell us what make and model of car you have—size of tires, etc.,—and we will send you an Auto-Meter.

DOW TUBES
Are the Most Economical

(The Best Tubes Ever Manufactured)

ONE YEAR'S CONSTANT SERVICE IN THE BOSTON FIRE DEPARTMENT

Dow Tire Co., New York, N. Y. Headquarters Fire Department, City of Boston, Bristol Street, Boston, July 20, 1908.

Gentlemen—Having used the Dow Non-Deflation Tubes since August 19, 1907, on the automobile used by Chief Mullen of this city fire department in his response to alarms of fire, I feel that, in return for the excellent results received from these tubes, I ought to inform you of same. Several persons have inquired of me as to their merits, and I have always spoken in the highest terms of them, but never felt that I could write you confirming my statements until such time as they had been in use for about a year.

We have given them all kinds of tests, and will truthfully say that they have withstood all punctures, and with the exception of "blowouts," which are liable to occur with any type of inner tube, they have given excellent satisfaction.

Trusting this letter may be of benefit to you, I remain, Yours very truly, (Signed) JOSEPH A. WEBBER, Lieut., Aide to Chief.

1909
Pope-Hartford Models

Pope-Hartford Model S, Standard Roadster, $2750

The POPE-HARTFORD 1909 models embody all that is best in automobile construction and will be conspicuous in the foremost ranks of the automobile world.

We invite comparison of the details of POPE-HARTFORD cars for 1909 with those of the world's best motor cars. Because of their perfection, refinement and elegance they will appeal to the superior judgment of critical and discriminating purchasers.

OUR 1909 LINE CONSISTS OF THREE MODELS:

A Standard Touring Car		**Price $2750**
A Standard Roadster	similar to the above illustration,	**Price $2750**
A Pony Tonneau Car	which will be illustrated in this space next week,	**Price $2750**

New and important improvements, not incorporated in any other motor car, are included in the POPE-HARTFORD 1909 CARS. Each improvement which we have added has been given a careful and thorough *test*, and our catalog, now in preparation, explains fully all the details and mechanical excellence of the new models. Let us place your name on our mailing list for an advance copy.

Agents almost everywhere. Correspondence invited with interested dealers.

Mayo Radiators Make a Good Car Better and Their Use on a Car is a Hall-Mark of Quality.

¶ Mayo Radiators are made in a quality shop. In their construction no expense is spared, no crude methods obtain. In their use complete satisfaction results.

¶ Mayo Radiators perform their functions well under all conditions—and conditions at times are exacting. It is at just such times that Mayo quality asserts itself.

¶ The engineer can eliminate possible radiator troubles from his calculations by the adoption of the best possible radiator. The test of years and use has proved that we make it.

¶ Our capacity limit on new contracts is rapidly being reached.

MICHELIN

REVISED PRICES NOW IN EFFECT

WHILE the unrivalled quality of MICHELIN tires, which has made them for years the STANDARD of the world, remains absolutely unchanged in any particular, the prices have been revised.

The unprecedented demand for MICHELINS from American consumers, which has kept our factory working twenty-four hours per day for the last twelve months, is a plain indication to automobile manufacturers and agents of what they may expect now that MICHELIN'S revised prices are being made known to the public.

FRANKLIN-1909

Bigness and bulk are not style.

You would pick out a Franklin automobile anywhere for its stylish appearance—its symmetrical lines and its perfection of detail, yet no Franklin has any unnecessary bulk or weight.

The Franklin Model H touring-car is a powerful capacious automobile—and looks it. Yet it weighs under 2500 pounds. Other seven-passenger automobiles are far bulkier and heavier, and vastly more expensive to own, but not one is more stylish.

All Franklins have the refined simplicity that is secured only through Franklin air-cooling, and the luxurious riding-quality possible only with the non-jarring Franklin construction. They have long wheel-bases and large wheels and tires. They are easy to manage and strong and safe. And of all automobiles Franklins are the most enjoyable to use.

Franklin closed carriages are especially noticeable for their beauty and style; and the line this year is exceptionally complete.

Model G is built with a brougham body making it very serviceable for doctors or others desiring a two-passenger closed vehicle.

Models G and D are furnished with landaulet bodies.

Model H is built as a limousine. This has the exceptional flexibility produced by the six-cylinder Franklin engine, and is the limit of perfection in closed carriages.

Besides these is the type K2 town-car, seating six. It is built upon our motor-cab chassis and is extra strong and durable.

Models—1909

G 18 H P touring-car, $1850.
G 18 H P runabout with hamper, $1750. With single or double rumble, $1800.
D 28 H P five-passenger touring-car, $2800. Or runabout, with single or double rumble, $2700.
H 42 H P seven-passenger touring-car, $3750. Or runabout, with single or double rumble, $3600.

THE BRAMPTON MOTOR CHAIN

All side plates on both sides of the Brampton Chain are stamped **"BRAMPTON."**

LARGE SALES and SMALL PROFIT with thousands of satisfied customers is our best advertisement. THE BRAMPTON CHAIN is made of self-hardening Steel; the strongest Chain in the World. All parts polished; fits sprockets (that are properly cut) without friction.

Some of the other chains may look like **THE CELEBRATED BRAMPTON CHAIN** because some of the other chain makers began to copy the design and shape of the **BRAMPTON CHAIN** links in 1904. They have improved somewhat on their copied design from time to time until these chains now look more like the **BRAMPTON CHAIN** than ever before. These chains somewhat resemble the **BRAMPTON** in appearance, but the manufacturers of such chains have been unable to copy the material —self-hardening steel.

NO CHANGE IN THE BRAMPTON

There has been no change in the design, construction, material or finish of the **BRAMPTON MOTOR CHAIN** in the past ten years.—**"ENUF SED."**

PRICE

The price being equal, it's presumable you want the best, and full value for your money. In such cases, the **BRAMPTON FILLS THE BILL,** and the prices are the same to manufacturers, jobbers, dealers and consumers as any other chain of equal size. We have in stock chains to fit all American and foreign cars.

YOUR 1909 CAR

You can have the new car that you order fitted with the **CELEBRATED BRAMPTON CHAIN** if you order it that way. No extra cost to either you or the manufacturer. All standard sizes in stock to fit American and Foreign Cars at the same price as the other chains.

SPECIAL CHAINS TO FIT THE INDIAN MOTORCYCLE.

APPERSON

The New Model O Apperson, Price $2450

Not an "assembled" car but built throughout in our own factory. Not an "experiment." It has been over a year on the road and has back of it our fifteen years of actual experience in the building of high grade motor cars.

SPECIFICATIONS:

Three, four or five-passenger bodies, optional.
Double ignition by magneto and storage battery.
Five lamps and generator.
Tire carrier, robe rail and tools.
Motor 30 horsepower. Wheel base 119 inches.

Model O Apperson, winner of its event at the recent Algonquin, Illinois, hill climb, showed greater efficiency than any other car of any make that ever competed in any event held under the auspices of the Chicago Motor Club.

We build higher-powered cars with either the four or six cylinder type of motor.

The Apperson line is the most complete of any offered by an established and successful maker of high grade cars.

TO DEALERS Owing to a largely increased output we are prepared to make selling agreements in open territory with a few reliable, live dealers. Write us.

Stoddard-Dayton

One Quality for all Models
One Price for all Buyers

Hundreds of motor enthusiasts will give a hearty welcome to this latest addition to the Stoddard-Dayton line.

Model 9-A—Price $2,000, f. o. b. Dayton.

This handsome light Touring Car is a duplicate of our regular Model F touring car which has always won such universal favor. Model 9-A is a counterpart of the larger car in everything except size and price. It will bear closest investigation and will not disappoint the motorist who wants a light Touring Car of Quality at a fair price.

Motor, valve-in-head; 35 H. P. Transmission, selective type. Gears, chrome nickel steel. Ignition, double system, when specified, at extra cost. Wheels, 34x3½ inches. Wheel base, 105 inches. Weight, 2,000 pounds. Equipment: Oil lamps, gas lamps, Prest-O-Lite tank, horn, tool kit, tire repair outfit. Price, $2,000, f. o. b. Dayton.

Model 9-C will be the Roadster companion to Model 9-A. Specifications will be the same, with the exception that wheelbase will be 110½ inches, and body will be along the same lines as our well-known 8-K, with different rear seat combinations, at slightly increased cost.

For 1909, Models F and K will be continued without change, except for refinement of detail.

Watch for announcement in near future of radical changes to be made in Model H for 1909. Write for Catalog.

ON TOP!! Continental TIRES

"Keep your eye on Continentals"

¶Motorists the world over claim "Continentals" to be the best and most durable tires made; manufactured in the **largest** tire factory where the watchword is not "how cheap"—but "how **well** can they be made," they prove their great value over other tires by giving **more miles for less dollars** to every user of them.

Cost—Production—Selling Price

¶**To-day** quantity is the governing power in almost everything. **Two thousand** (2000) **and more Continental Tires** are manufactured every twenty-four hours—consequently our purchasing facilities are unequalled. **We sell Continental Tires** at a profit which has for a basis of calculation our enormous buying and producing ability

Continental Tires at Lower Prices

¶The above achievements mean that our success is **your** saving and **not** that we are **obliged** to reduce the **quality** and price of **our** product to meet **price** competition. **We share with you** our success by offering you a tire from which you can obtain the **most** amount of mileage **for the least** investment of money.

¶**Reduced tire expense means using Continental Tires.**

Rambler

Model 34

Price, $2,250
Other Models, $1,200 to $2,500

TRY IT ON THE HILLS

Test this car at half speed on a hill or sand road where power and every ounce of it is needed. Notice how steadily and powerfully it pulls when running slowly under load.

The capacity of the offset crank shaft for doing this extra work is most noticeable at low engine speeds. All that power which in other engines is lost through friction on the bearings and cylinder walls, is added to the driving force by the Rambler offset crank shaft. It reduces friction; eliminates hammer on bearings; gives more power.

The straight line drive delivers the power direct and with least frictional loss to the rear axle. Let us demonstrate these features and the silence and the comfort of this car.

Tell our nearest representative to call at your home and take you to your place of business some morning in a Rambler. Or write your name and address and "Model 34" on a postal and mail to us today.

THE MOTOR WORLD

Volume XVIII. New York, U. S. A., Thursday, September 3, 1908. No. 23

MUST FIGHT CASE ON ITS MERITS

Court Decides Rushmore vs. Badger Suit is Unlike Others—Suspension of Injunction is Continued.

Although Samuel M. Rushmore, of Plainfield, N. J., tried to show through his attorneys that the Badger Brass Mfg. Co. of New York, was in the same class with the Saxon Lamp Co. and the Manhattan Screw & Stamping Works, against whom he had secured injunctions following allegations of "unfair competition," Judge Lacombe, in the United States Circuit Court for the Southern District of New York, handed down a decision last Thursday making it clear that the court considered the circumstances in the case of the Badger company quite different, and that the favorable decision obtained by Rushmore in the other cases cannot be extended to apply to the Badger Bras company.

Through its attorneys, Joline, Larkin & Rathbone, the defendant company agreed to give bond to any reasonable amount, but asked that the injunction with which it was threatened be further suspended until a final hearing on an action directly against it by the plaintiff Rushmore. Judge Lacombe met the defendant's wishes in this respect and fixed the bond for the protection of Rushmore at $5,000, and also made an apportionment of the time in which it will be necessary for the plaintiff to take the necessary testimony to prosecute his case. This action entirely separates the litigation against Saxon and Manhattan from the controversy with Badger Brass.

The time for the taking of testimony is in Lacombe's decision apportioned as follows: Complainant's prima facie, 30 days from the first Monday in September; defendant's reply not exceed 45 days thereafter; complainant's rebuttal not to exceed 15 days thereafter. When rebuttal is completed, motion by either side will be entertained to place on the calendar. As in the other cases, the prosecution will be waged on the ground of alleged "unfair competition" in relation to alleged imitation of the Rushmore "flared front" designs.

Record Year for the Rambler.

Thomas B. Jeffery, head of T. B. Jeffery & Co., Kenosha, Wis., returned from Europe on Friday last. He had been absent some two months.

When Mr. Jeffery reached his factory in Kenosha, Wis., he received the welcome news that all records for midsummer sales of Rambler cars were broken during the month of August. Instead of the falling off which is usual during the month of August in other years, the sales of Ramblers were three times as large as the sales of August, 1907.

Although the year of 1907 was the greatest in the history of the Rambler business, at the end of the fiscal year of 1907 and 1908 the volume of business was shown to be greater than that of the preceding year, which in view of the widespread financial disturbance is the more remarkable.

Southworth and Koehler Shift About.

A. G. Southworth, for several years the New York agent for the Pope cars, has relinquished that account and accepted the management of the Buick branch, which temporarily will be located in the Southworth store on Broadway. The H. J. Koehler Sporting Goods Co., which previously handled the Buick, has taken the agency for the E. M. F. car. The A. G. Southworth Co., under which style Southworth operated, will wind up its affairs.

Kissel Succumbs to His Wounds.

Louis J. Kissel, president of the Kissel Kar Co., Hartford, Wis., who on August 19th, was shot three times by an enraged employe, succumbed to his injuries on Friday last, 28th ult. Mr. Kissel was 70 years of age and long had been prominent in the affairs of his locality, his automobile factory being but one of several large enterprises in which he was concerned.

MORE ROOM AT THE PALACE SHOW

Rearrangement of Floor Plans Will Permit Increased Number of Exhibitors—Date Set for First Allotment.

According to the prospectus issued this week, the first allotment of space in the American Motor Car Manufacturers Association's show in Grand Central Palace, New York, December 31-January 7, will be made October 8th. All applications received up to the first day of that month will be given equal consideration in the drawings, save that members of the association will draw first for the space in the vehicle section, other than that on the main floor which has been set aside for the importers, who will make their own apportionment, as will the members of the Motor and Accessories Manufacturers.

The general disposition of exhibits will be practically the same as at the previous shows, as follows:

Pleasure vehicles: Main floor and part of gallery floor. Commercial vehicles: First gallery floor. Taxicabs: First gallery floor. Motorcycles: First gallery floor. Tires, Parts and Accessories: Main gallery and first and second gallery floors.

The usual display of balloons and other aerial craft will occupy the top floor of the building, but the moving picture attraction will be eliminated and the space be devoted to accessories. A rearrangement of the floor plans also will afford space for additional exhibitors.

Practically the same rules that governed former shows will prevail. The admission fee will be 50 cents, save on Tuesday, January 5, which will be "dollar day." "Special invitation" tickets—heretofore termed "trade tickets"—will be sold to exhibitors in lots of not less than 100 at 20 cents each. Exhibitors will not be permitted to sublet space nor to display goods which they do not actually manufacture or sell. Signs, decorations and tags will be of uniform design.

Brooklyn, N. Y.—A. W. Blanchard, Inc., under New York laws, with $25,000 capital; motors. Corporators—Alva W. Blanchard and Lucy Blanchard, 20 Waldorf court; A. Neil Wilcox, 111 Pacific street, Brooklyn, N. Y.

New York City, N. Y.—Walter Christie Automobile Co., under New York laws, with $400,000 capital. Corporators—Van S. Howard, 308 West Forty-eighth street; C. Colgate Moore and G. W. Moore, 602 West Fifty-second street, New York City, N. Y.

Ajax Establishes Two New Branches.

The Ajax-Grieb Rubber Co. this week opened two new branches, one in Philadelphia, the other in Kansas City. The former is located at 316 N. Broad street, and is in charge of Joseph Keir, who formerly was with the Michelin company. Keir is a resident of Philadelphia and is an experienced tire man, having been engaged in the business for the past five or six years. The Kansas City branch is located at 1422 Grand avenue. Its manager is Enoch Graf, for many years past buyer of all rubber goods for the Schmelzer & Sons Arms Co. of Kansas City.

Van's Creditors Allege Queer Methods.

If half of the allegations of his creditors proves to be true, Frank Van Tassel, who was practically all there was of Van's Auto Tire Co., 792 Seventh avenue, New York, certainly made haste to fortify himself against the proverbial rainy day and was not particularly circumspect in his methods of doing so. Three creditors, the Republic Rubber Co., $236; Hartford Rubber Works Co., $652, and Mutual Auto Accessories Co. of America, $208, have filed a petition in bankruptcy against Van's company, and in doing so they allege that the company is insolvent, and had removed and concealed its entire property except some rubber tools and machines of small value; had purchased upon credit goods largely in excess of the amounts usually bought in the regular course of business, and immediately thereafter disposed of the goods, some at less than cost, and the remainder concealed in some place unknown to creditors, and the company kept the proceeds. It was also alleged that within the last month Frank Van Tassel, the president and active manager of the business, has been absent from the store, has refused to see creditors or to answer inquiries relative to payment of their claims. The company was incorporated February 25, 1908, with a capital stock of $10,000. After considering the creditors' petition, the court designated Robert A. Inch as receiver of the concern.

Haynes-Apperson Amalgamation Denied.

Rumors of a proposed consolidation of the Apperson and Haynes automobile companies, of Kokomo, Ind., have been so persistent as to have gained considerable credence in the West. When approached on the subject, however, Elmer Apperson, who would be in a position to know if anyone would, replied to inquiries with the simple statement, "It's all news to me."

Partners Fall Out; Suit Follows.

W. H. Byrne has been appointed receiver for the partnership property of the West Side Auto and Transportation Co., of 2180 Broadway, New York, in a suit brought by Michael O'Connor against his partners. Thomas Doherty, Thomas Flaherty, and Charles Cantillon, for a dissolution of the partnership. They began business in May. The liabilities are $500 and the assets $5,000.

To Produce Palmer's Truck Tire.

The Palmer-Hawkins Rubber Tire Co., Akron, which recently was incorporated under the laws of Ohio, will manufacture the sectional motor truck tire invented by H. A. Palmer. Mr. Palmer himself is president and general manager of the company and A. W. Hawkins, secretary-treasurer.

Thomas Company Engages a Lecturer.

E. S. Thomas, for many years lecturer for the National Cash Register Co., has accepted a similar position with the E. R. Thomas Motor Co., of Buffalo. Mr. Thomas is to make a photographing trip over the route followed by the Thomas car through Europe and Asia in winning the New York-Paris contest, after which he will undertake an extended illustrated lecture tour for the concern.

Horsey to Handle Empire Tires.

E. T. Horsey, who for several years has handled Continental tires in the territory, has obtained the representation for the Empire tires for the greater part of Ohio and has located at 1268 Euclid avenue, Cleveland. He will operate under the title Empire Tire Agency.

In the Retail World.

Chanslor & Lyon, who conduct supply houses in Los Angeles and San Francisco, are preparing to establish a store in Seattle. It will be opened about October 1.

Frederick Livingston, formerly with the Ford Motor Car Co., New York City, has established the Morristown Motor Car Co., at Morristown, N. J. He will handle the Ford and the Jackson cars.

Otto Owen and B. C. Buxton have organized in Chicago the Reo Automobile Co. and have established salesrooms at 1218 Michigan avenue; they will handle Reo cars not only in Chicago, but in northern Illinois.

The John Deere Plow Co., of St. Louis, one of the largest and oldest agricultural implement houses in the West, has "gone into" automobiles. They have taken the representation for the Jackson car on which they have been alloted a generous slice of western and southwestern territory.

C. N. Reed and C. S. Walters, of Tarentum, Pa., have formed the Tarentum Auto Co., to conduct a garage and salesroom. A brick building has been erected at Mill street and West Seventh avenue, and a complete machine shop has been fitted up in the basement. The main floor will be occupied as salesroom and garage.

M. S. Brigham, manager of the Cadillac Motor Car Co.'s retail department in Detroit, is preparing to remove to the other edge of the continent. After a "prospecting tour" to the Pacific coast, he has secured the Cadillac sales agency for the State of Washington, and will establish himself in Seattle, from which point the business will be handled.

The E. C. Long Mfg. Co., of Hannibal, Mo., having consolidated with the Bluff City Plumbing and Heating Co., is said to plan the erection of a three-story concrete building to contain a fully equipped garage. The principal business of the consolidated companies will be handling and selling automobiles and manufacturing electrical and plumbing supplies.

John P. Schneider, one of Detroit's pioneer dealers who now is handling Franklin cars, has leased for a long term of years the property on the southwest corner of Woodworth avenue and Bogg street, Detroit, 131 by 160 feet, on which will be erected several stores and one of the finest modern garages in the city, the garage to be built in the rear of the store property. Plans for the building are now being prepared by architects.

To Make Motor Buggies in Cincinnati.

The Buggy Car Co. has been incorporated under the laws of Ohio, with a capital stock of $20,000, and will locate on Fifteenth street, Cincinnati. The company succeeds to the business of the Postal Auto and Car Co., of Bedford, Ind., which will be transferred from that place to Cincinnati.

OFFERS M. A. M. 5 PER CENT EXTRA

N. A. A. M. Paves Way for Settlement of Chicago Show Controversy—Rim Question Bobs up Again.

It now seems probable that the Motor and Accessory Manufacturers, Inc., and the National Association of Automobile Manufacturers will be able to reach an agreement in respect to the price of space at the Chicago show; at any rate, the executive committee of the N. A. A. M. at its meeting in New York yesterday paved the way in that direction by resolving to offer the M. A. M. an additional rebate of 5 per cent. on the price of all space occupied by its members, in other words, to make the rebate 20 per cent. instead of 15 per cent., as on the occasion of the previous show. The N. A. A. M. set September 10th as the limit for the acceptance of the proposal. Pending the M. A. M. decision, the show literature which is ready for the printer, is being withheld. As will be recalled, the members of the Motor and Accessory Manufacturers, at their meeting in Atlantic City last month, voted not to exhibit at the Chicago show unless the promoters thereof, the N. A. A. M., accorded more favorable terms.

At yesterday's meeting of the National Association, the rim subject was brought up for discussion, but further action was postponed until the October meeting which will occur on the 7th. On that date the show committee will convene at 9.30 a. m., the executive committee at 11.30 a. m., and at 3 p. m., the first allotment of space at the Chicago show will be made.

Outside of the regular routine, the only other business transacted yesterday was the transferral of the membership of the Wayne Automobile Co. to its successor, the Everitt-Metzger-Flanders Co.

Bright Prospects in Lone Star State.

W. F. Reynolds, who covers the Southern States for the H. H. Franklin Mfg. Co., reports that in Texas, particularly, the outlook for the automobile business is unusually promising. The crops are good, the roads are much better than fancy pictures the climatic conditions are favorable, and the inhabitants are awake to the advantages of motor travel. Reynolds none too shyly hints that owing to the scarcity of water in many parts of the State, the people are predisposed to use the air-cooled cars.

Speaking of the roads, he states that on one of his trips he covered 98 miles, the road being as "level as a floor, with not a rock on it, not a gate to open, not a stream to ford, nor a dog to bark. It is open the throttle wide and whiz 100 miles away in quick time."

"Since the Lone Star automobile route to Seminole was started it has never missed a daily trip," continues Reynolds. "It carries five sacks of mail a day from Midland to Seminole, Andrews, Shafter Lake and Monument, N. M., and now covers a route within nine hours that formerly required two days travel. The old fashioned pony express is very much out of date. Seminole now gets mail in five hours which once took seventeen. On the way to Seminole the road is just sandy enough to keep from getting muddy when it rains. There is not a big hole or creek to cross in the entire distance.

"Midland has three good garages, with another in sight, and plans are now afoot for an automobile line from Seminole to the New Mexico border, and from there to Roswell, N. M., a distance of 268 miles from Midland. Seminole has agreed to its part of the work, and Roswell will look after its side. It is expected that within a few months automobiles can be run easily the entire 268 miles, 160 miles being already in operation."

Pope Creditors Seek Another Dividend.

In the Chancery Court in Newark, N. J., on Tuesday last, 1st inst., Percy S. Bryant, of Hartford, Conn., counsel of the creditors' committee, obtained an order directing the receivers of the Pope Mfg. Co. to show cause on September 8 why they should not be compelled to pay a third dividend of 25 per cent on all approved claims.

In the petition filed by Mr. Bryant he had incorporated a statement of the Pope concerns, dated August 31, showing cash deposits in bank aggregating $1,152,561.99. Of this amount, however, the sum of $345,432.95 represented assets of other insolvent corporations owned by the Pope company, and being thereby not available for the payment of a dividend to its creditors.

September 8 is also the return day for the rule granted by Vice-Chancellor Howell directing parties in interest to show cause why the Pope receivers should not accept the offer of $200,000 made for the Pope-Waverly plant at Indianapolis.

Winton Adopts Automatic Tire Inflator.

Quite the most radical innovation that has been adopted in several years by any of the leading automobile manufacturers was announced this week by the Winton Motor Carriage Co. It is substantially an automatic tire inflator which will render unnecessary the use of the time honored hand pump. It will be applied to all Winton "Sixes," and consists of an extension of the Winton self-starting system, the pressure tank of which will be tapped for tire inflation purposes. Attached to the self-starting cock on the dash is a nipple to which may be screwed a rubber tube leading to the tire to be inflated. By the opening of the cock the pressure of the tank is at once exerted on the tire, which fills with a rapidity and lack of labor more than pleasing to the man who has had experience in pumping an automobile tire by hand.

MITCHELL MEN IN CONVENTION

Meet in Racine as Guests of the Company—Gold Watches as Souvenirs—Big Orders are Booked.

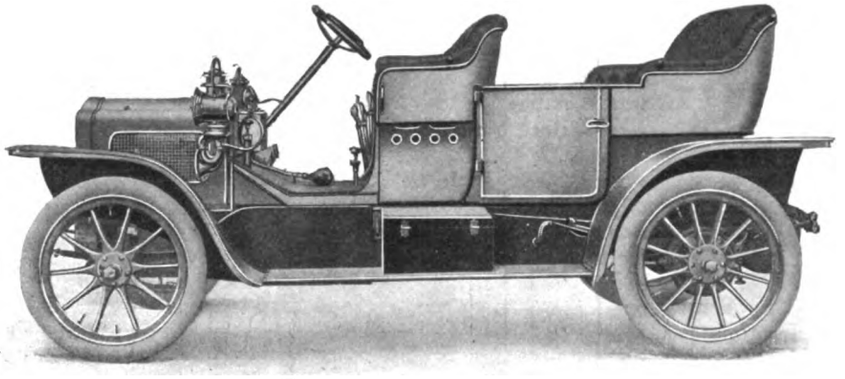
Apart from newspaper men and other guests, 97 Mitchell agents responded to the invitation of the Mitchell Motor Car Co. to talk business and make merry on August 27, 28 and 29, on the company's native heath, Racine, Wis. The occasion proved one that none of those who participated is likely soon to forget. The "making merry" was of the sort that leaves a lasting impression. Nothing was done by halves, as was evidenced by the souvenir of the gathering which took the form of a solid gold watch inscribed with the recipient's name and other wording appropriate to the occasion. Everything else was "on the house." Railroad fares and all other expenses were borne by the Mitchell company. The agents were its guests in fact as well as in name, and they were treated accordingly.

While the festivities played large parts, they did not overshadow the serious side of the conference, for such it was. "Talking business" occupied much of the three days and the inspection of plant and product, the interchange of opinions and the acquaintances formed did much to knit closer the Mitchell fabric.

The newest addition to the Mitchell line, the $1,500 light touring car, caught the fancy of the agents and as indicating the trend of the times, it is significant that of 2,944 cars for which signed orders, with deposits, were placed during the three days, the new model was in uppermost demand. There was nothing indicating depression or doubts of the future apparent at the convention. "Good prospects" was the common report and the men backed their beliefs with their orders.

It was a very busy three days for the visitors, but an even busier one for the Mitchell heads, William Mitchell Lewis, J. W. Gilson, G. Vernor Rogers and John Bate.

Clinton Goes from Trade to Sport.



Harry T. Clinton, head of the publicity department of the Association of Licensed Automobile Manufacturers, has resigned that position. He has engaged to become secretary of the contest committee of the Automobile Club of America, having had some previous experiences as a member of the American Automobile Association's racing board.

New Producer of Rubber Accessories.

The Empire Rubber Mfg. Co. has been formed in Akron, Ohio, to manufacture automobile supplies and rubber cement. Its plant is located at 200 East Exchange street, in that city.

THE 1909 WHITE STEAM CARS

During the coming season, the White Steam Cars will be built in two distinct models which, while differing widely in size, in power and in price, will follow the same general lines of construction. The horse-power ratings of these cars are based on the actual power delivered at the rear wheels, not merely on formulas or on the power delivered at the engine.

The larger of the new cars is known as the Model "M." It is rated at 40 steam horse-power and sells for $4,000., f. o. b. Cleveland, equipped with acetylene headlights and tank, oil lamps, horn and tool kit. The wheel base is 122 inches; the front tires 36 x 4 inches and the rear tires 36 x 5 inches. The car is regulary equipped with a straight-line seven-passenger body.

The smaller of the cars (shown in the above illustration) will be known as the Model "O." It is rated at 20 steam horse-power and sells for $2,000, f. o. b. Cleveland, equipped with oil lamps, horn and tool kit. The wheel-base is 104 inches and the tires, both front and rear, are 32 x 3½ inches. The car is regularly equipped with a straight-line five-passenger body.

The power plants of the two models are identical in design, the only difference between them being in the dimensions of the various parts. The principal mechanical change in the new cars, as compared with previous White models, is in the engine. The new engine is fitted with the Joy valve mechanism, instead of the Stephenson valve mechanism. The valves are driven from the connecting rods, as are the pumps. The eccentrics are done away with and the cylinders are brought close together, permitting the use of a short one-piece crank-shaft, with but two main bearings. The number of parts in the engine is reduced by one half and the entire construction greatly simplified.

As in previous models, the generator — the simplest steam-making device ever designed — consists simply of a series of coils of steel tubing joined together. The regulating system, whereby the temperature and pressure of the steam remain constant without in any way engaging or requiring the attention of the operator, is similar to that in the 1908 cars.

A Circular containing full details of the New Models will be sent on request.

The Fraud in Lubricants.

Despite the long and unremitting effort made to drill into the brains of all who have to do with motor cars, that nothing connected with their use is of such vital importance as the item of proper lubrication, it appears as if the full force of the truth never will be instilled into not a few minds and, what is almost incomprehensible, it seems equally plain that cupidity—the desire to add a few miserable dollars to their profits—on the part of many men engaged in the automobile business is playing a part in defeating the good work.

There is no man in the trade who is fit to remain in it who does not know that the term "proper lubrication" means not only proper lubricants regularly applied in proper quantities, yet evidence accumulates that the number of men who deliberately and unscrupulously make use of inferior oils is quite numerous. Only this week a manufacturer of oils offered the statement that the practice of substituting a cheap grade of paraffin or of neutral oil for oils of known brands and quality is "widely practiced."

"It is practiced, too, by a class of dealers and garages that ought to be above such petty trickery," he adds. "I know of large garages that sell from four to six brands of oil and they buy only one, and pay less than 15 cents a gallon for it."

These strong and rather sweeping assertions would be difficult of belief had they not been proven true by the manufacturer of a well known brand of oil who in a recent round-up of Philadelphia garages discovered eight out of thirteen of the places visited engaged in substituting inferior lubricant for his own high grade product, and, of course, exacting the price of the latter. This particular manufacturer promptly applied the most effective corrective measure. He instituted legal proceedings against each and all of those engaged in the fraud, which is the proper definition of the practice. The astounding results of this "raid" suggests that similar proceedings in other cities may prove equally fruitful.

Regretable as the statement may appear, it is debatable whether the majority of the men engaged in a strictly garage business are truly interested in the welfare of the automobile industry, which is to say, in the satisfactory service of the cars which are housed on their premises. Their unscrupulousness in respect to the sale of lubricants is but one of the indications in that direction. But that many men who sell cars as well as store them stoop to the petty fraud is not readily conceivable. They should be so greatly concerned that their cars render satisfactory service that anything that would influence service of the other sort should be jealously guarded against; and as the cheap nondescript lubricant is an influence of the sort, it scarcely seems probable that they would invite trouble and defraud their patrons by resort to fraudulent substitution which substantially is a form of petty larceny. It certainly would be instructive to discover how many of such dealers are not above the practice complained of.

As proper lubrication often means the difference between the efficient and the inefficient service of a car, the difference btween long life and short life and all the trouble and expense that lies between, the subject is one that seems not too small to seriously merit the attention, if not the co-operation, of the automobile manufacturers themselves. The cheap "paraffine" and the cheap "neutral" oils which are dispensed by the unscrupulous men of the business are the factors responsible for carbon deposits and automobile manufacturers well know that these deposits not only represent imperfect combustion, which means inefficient lubrication, but that they are the cause of some of the most vexatious and too often unsuspected ills to which a motor is heir.

The Two Types of Designer.

From the human and psychological side there are two distinct schools of automobile design. This is shown by the two differing methods in which designers approach the problem of laying out a new car. While every designer is more or less individual in his methods and in his own attitude toward his work, he of necessity falls into that class, on the one hand, which believes in creative work as a duty, or into that, on the other, which regards the judicious adaptation of practice proved successful in service as the true function of the present day designing department. In their extremes these two governing ideas spell freaks and stagnation, respectively.

A concrete instance of the "adaptation" method is found in a well known high powered touring car model which has enjoyed deserved popularity for several years. Preparatory to making the first drawings for this model the designer studied every available type of American and foreign car then on the market, not only with a view to acquainting himself with the general status of the art, but for the more specific purpose of taking the actual dimensions of each, from axle and gear sizes to wrist pin diameters and cylinder wall thickness. Reams of paper were filled with the records of these measurements and by weeks of subsequent figuring, the averages of practice in the more successful cars of about the size and type planned for the new product, were approximated. Motor design, valve size calculations and the selection and disposition of metal in the frame and the transmission system were all evolved from the current practice of other designers. That the resulting car was a marked mechanical and commercial success, bearing reproduction through several seasons without change, in this instance seemed to offer a complete justification of the designer's method in addition to being an evidence of his judgment and skill in wise "adaptation."

Radically opposed to this method is the

Digitized by Google

bold work of numerous American and foreign designers in disregarding as far as possible the products of other minds and striking for new and original solutions for the problem presented. Eager for data as to strength of materials and for that complete equipment of the most advanced knowledge concerning the physical and mechanical phenomena to be considered in capable car designing, they spurn anything suggesting slavish imitation of detail, and having created for themselves certain ideals or goals they set about attaining the results they seek, by inventive methods. Naturally enough it is from the "creative" designers that the very best and the very worst motor car conceptions have come, depending upon the ability and knowledge back of the more original features.

The masters of "creative" design, however, do not close their eyes to the work of others through a desire to ensure mere "differentness." That is left to the smaller minds or to the gentry who devise novelties simply to catch suckers or angels. The real purpose is a deeper one and is based on the recognized fact that in invention the most direct and happy solution of a problem is likely to be more easily reached if the mind at work on it is not lead along paths pursued by others. It requires a peculiar quality of intellect to be able to feed on all the facts and data gathered by others without absorbing at the same time the opiates of imitation and copying.

The quick and impulsive patronage that has been given to radically new designs having appearance of superior qualities over previous types, by liberal and enthusiastic buyers, has been an unique feature of the automobile business, in marked distinguishment from the general treatment accorded daring improvers in other lines in the past. The encouragement thus given the "creative" school has in no small measure accounted for the rapid progress and development of the art. But as the composite car more nearly approaches perfection the dangers from the commercial standpoint in radically new ideas multiply, since time tried practice can be called upon to support the "conservative" and "adapted" designs which commercially astute makers offer.

COMING EVENTS

September 5, St. Paul, Minn.—Minneapolis Automobile Club's race meet at State Fair, Hamline track.

September 5-9, Los Angeles, Cal.—Automobile Dealers Association's reliability run to San Francisco.

September 7, Wildwood, N. J.—Motor Club of Wildwood's race meet.

September 7, Denver, Col.—Denver Motor Club's 300 miles stock car race.

Sept. 7, Columbus, Ohio.—Columbus Automobile Club's race meet.

September 7, Lowell, Mass.—Lowell Automobile Club's 200 miles road race, on Merrimac Valley boulevard.

September 7, Columbus, Ohio.—Columbus Automobile Club's race meet.

September 7-8, Morris, Ill.—Chicago Motor Club's two days' race meet, Chapin Park.

September 7-12, Hartford, Conn.—Connecticut State Fair Association's outdoor show and grand circuit races at Charter Oak Park.

September 11-12, Brighton Beach, L. I.—Motor Racing Association's 24 hours race, Brighton track.

September 11, Springfield, Mass.—Springfield Automobile Club's hill climb on Wilbraham hill.

September 12, Louisville, Ky.—Louisville Automobile Club's race meet at Churchill Downs.

September 14, Chicago, Ill.—Chicago Motor Club's annual economy run.

September 16-17, Long Island—New York Automobile Trade Association's mechanical efficiency test, New York to Montauk Point and return.

September 23-24, New York City.—Dust trials, smokeless exhaust and brake tests, under auspices of New York Automobile Trade Association, Central Park.

September 20, San Francisco, Cal.—Olympic Athletic Club's race meet at Tanforan Park.

September 20-30—Kansas City Automobile Club's endurance run, Kansas City, Mo., to Oklahoma City, Okla., and return.

September 23-24, Boston, Mass.—Bay State Automobile Association's 24 hours endurance run, Boston to Bretton Woods, N. H.

October 6-9, Chicago, Ill.—Chicago Motor Club's 1,000 miles reliability run.

October 7, Philadelphia, Pa.—Quaker City Motor Club's 200 miles road race, Fairmount Park.

October 10, Long Island—Elimination trials for Vanderbilt cup contest.

October 17, Hartford, Conn.—Automobile Club of Hartford's hill climb, Avon Mountain.

October 24, Long Island.—Vanderbilt cup contest.

November 26, Savannah, Ga.—Automobile Club of America's (New York), 400 miles outlaw race for foreign cars.

December 31-January 7, New York City—American Motor Car Manufacturers' Association's annual show in Grand Central Palace.

January 16-23, New York City—Association of Licensed Automobile Manufacturers' annual show in Madison Square Garden.

January 23-30, Philadelphia, Pa.—Philadelphia Automobile Trade Association's annual show.

February 6-13, Chicago, Ill.—National Association of Automobile Manufacturers' show, Coliseum.

Radiators and Overheating.

Childlike pride which many men exhibit in a radiator system that under almost all conditions of service is "as cool as a cucumber," will be given a rude shock by the conclusions of the investigators of radiator problems which are printed in another column and which are to the effect that reduction of half of the present size would serve as well. They make clear that radiators which cool the water in the cylinder jackets much below 160 degrees Fahr., adversely affect the efficiency of the engine. For the most perfect running an explosive motor requires the highest heat it can stand without inducing preignition or endangering cylinder walls or piston parts.

While the fear of the dread "overheating" has in the past lead many owners of a small car to install disproportionately big radiators, few of them have been able to account for the reduction in maximum power which followed the change, though it was in nearall cases due to too great a cooling of the engine. The ideal for a cooling system is one that will heat up to the temperature of maximum engine efficiency as quickly as possible, and will then hold to that mark as long as the motor is running.

If the flow of water through the circulation system is free and thorough, the radiator should heat up rapidly after the engine is started. A radiator that stays cool shows either that it is too big for the engine or that the circulation is clogged.

"It is better to be sure than to be sorry," as some of the men who are mixing with the "outlaw" movement will do well to realize before getting in too deeply. The exception is extremely rare when "outlaws" have not had to bend their necks and partake of a most unsavory dish.

THE RACE NOT TO THE SWIFT

Minneapolis Hill Climb Ruled by Mathematics—Webster Makes Best Time, but Clark Wins by Formula.

Following the example of Chicago's exponents of higher epithetics as applied to automobile hill climbing and the subsequent relation of values thereto as evolved therapeutically, whatever that may mean, Minneapolis's high priests of calculus filled their reddwarfink-pencils and figuratively dipped into phases of higher mathematics as applicable to loga and other rithms on Saturday last, 29th ult. The Minneapolis calculators finished up the job quicker than did the Windy City figurers a couple of weeks ago, but to do full justice to both sides it must be explained that Chicago had only its own city to draw from plus the village schoolmaster at Algonquin, while at the Minneapolis hill climb all the mathematical professors from the Twin Cities—which includes both Minneapolis and St. Paul—were out to the Cedar avenue hill in force and automobiles.

It is not quite plain just which formula was used in determining the results of the Minneapolis ascending test. Some have it that the square root of the root of all evil, raised to the nth power and divided by the difference of the cylinder capacity of the car and the tanking capacity of the driver, multiplied by the square of the voracity of the latter, was the formula that was employed. On the other hand it is advanced that the formula went something like this: Cylinder capacity of the car multiplied by the time in seconds, divided by the weight of the car and driver. Whichever formula is correct that one was used, and winners were evolved in the ten classes, which wasn't very hard to accomplish in at least three of the classes; they had one entry in each.

Despite the fact the hill was located ten miles south of the court house, a large crowd enthused over the sport, and more than 300 non-competing machines, were lined up alongside the course. The upstretch measured 2,136 feet, and with a sharp curve midway, there were sufficient thrills to satisfy those who congregated at that point. There is a rise of 105 feet in the course. A speedway of gravel, while not in as perfect condition as it might have been, made a splendid track for the drivers to show off the best qualities of their machines. It is estimated that at least 300 cars were parked along the roadway and that 1,500 people saw the climbing contest. So great was the crowd at the midway curve and at the finish that the efforts of two policemen were necessary at the curve to keep the spectators from danger, and the officials at the finish had more than they could do.

As frequently happens in formula hill climbs, the car which made the fastest time did not necessarily win the class in which it made the fastest time. For instance, in class C, Gordon Bird in a Corbin car, climbed the hill in 33⅕ seconds, while H. J. Clark, in a Pope-Hartford car, required 43⅘ seconds to do the trick, yet the latter was evolved the winner. This was the only perverse case which occurred, however.

Class A was for motor buggies of the high wheel type and a Holsman driven by W. C. Rader carried off the honors by climbing the hill in 1 minute 12 seconds, which gave it a percentage of 6.547. Two Buicks, driven respectively by Charles Nyquist and D. W. Onan, finished in those positions both in respect to time and percentage.

Three of the classes resulted in walkovers, but the single entrants made the runs, nevertheless, the winners being A. C. Miller, Stoddard-Dayton, and Yaul Hoffman, who won two classes with his PierceArrow of endurance run fame. There were three other classes in which the formula was not used, the fastest time countinfi, and in these Gordon Bird, Corbin, was returned a winner in Class G, with George H. Seeley, Moon, a winner in Class I. Bird's time was 33⅗ seconds, and Seeley's 47 seconds. The class for steam cars went to George D. Webster, who defeated C. G. Sigwald by 9⅕ seconds in 30⅗ seconds, the fastest time of the afternoon. Bird lived up to the suggestiveness of his name by making the fastest time among the gasolene entrants. The summary:

Driver.	Name of Car.	H.P.	Cyl.	Wt.	Time Sec.	P.C.
	Class A					
W. C. Rader	Holsman	12.4	2	1,105	72	6.547

EXTEND VANDERBILT ENTRY LIMIT

Cup Commission Allows Another Month—Entries in Hand and in Prospect—Steel Grandstand Ordered.

Five American and one foreign car constituted the total entry list for the Vanderbilt cup race on the 1st inst., when the list was to have closed. In addition to these, no less than half a dozen American makers have promised to enter, while two or three who have not definitely promised are expected when the time comes. In order to give them more time to reach a decision, the closing date for entries at $1,000 each, has been extended to October 1.

The actual entries to date are a six-cylinder Acme, a Mora, two Knoxes, and a Chadwick "six," while the only foreign entry is Robert Gray's Mercedes. The following cars have been promised, but not yet entered: Thomas, Locomobile, Roebling, Pennsylvania, Frayer-Miller, and Pope-Toledo. George W. Young's 100 horsepower Fiat also is a possible entry.

A. L. Riker has announced that one Locomobile is being prepared by the company with the expectation of putting Joe Tracy at the wheel, as in previous Vanderbilt races, and that a second Locomobile also may be entered. It is also stated that

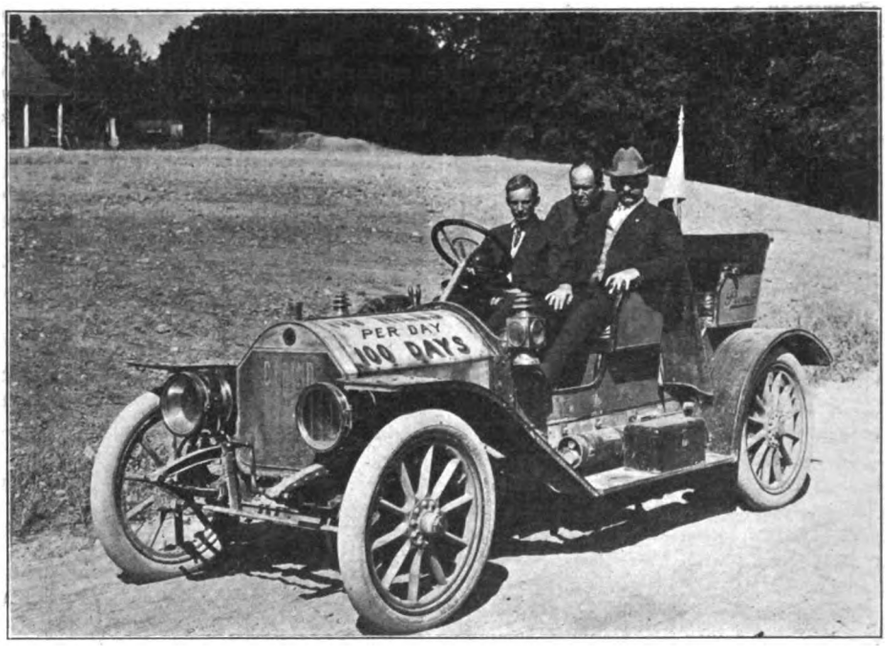
Digitized by Google

syndicates have been formed to enter the 1906 Thomas, Pope-Toledo and Frayer-Miller cup cars. Out in Trenton, men are working on the Roebling machine, while of those cars already entered the Acme is being tested out almost daily at Reading, Pa., and the Knox people are working on their team of cars at Springfield, Mass. The Chadwick and Mora entries are designed for great speed and will shortly be put through some severe road testing.

While unfriendly critics have been circulating stories of the probable abandonment of the contest, the Vanderbilt cup commission has ordered the erection of the steel grandstand, which will seat 10,000 persons. At present there is some doubt about an elimination race being held, but the cup commission insists that enough entries have been unofficially assured to necessitate one.

Extra precautions are to be taken this year as regards patrolling the course. the Nassau county supervisors having specified in their agreement with the Vanderbilt cup commission that more adequate protection for the public shall be provided.. Special officers and flagmen in white uniforms will line the entire length of the course. In addition to these officers the association, according to a statement made recently by A. R. Pardington, will furnish about 1,200 uniformed and armed guardsmen to patrol the roads, and that they will be men of better quality than the squads of "ornaments" who dotted the course in previous years.

Several drivers already have been nominated for the entered cars. Charles Basle and William Bourque, who are to drive the Knox cars at Lowell, Mass., on Labor Day, will handle that company's two entries in the Vanderbilt. It was Basle who scored a world's record kilometer at Ormond Beach in H. L. Bowden's Mercedes three years ago, and he has since made several notable performances abroad. Emile Stricker has been engaged by Robert Graves to pilot his Mercedes. Stricker has been driving Porthos cars in the Grand Prix and other European races the last few years and it is to this driver that Louis Strang, who was his pupil, attributes much of his success as a racing driver. George Salzman will be the probable driver of the Thomas entry which has been assured.



Confusing Two Well Known Names.

The similarity of names has on several occasions caused confusion in the affairs of E. R. Thomas, the Buffalo manufacturer and E. R. Thomas, the New York banker and speed maniac. In connection with the revoking of the latter's license in consequence of his recent smashup, a Trenton (N. J.) daily paper informed the public last week that the victorious New York-Paris Thomas car had just had its license revoked by Commissioner Smith of New Jersey. Trenton, which is noted chiefly for having produced such a celebrity as Miss Rose Stahl, should purvey its news a little more accurately.

CENTURY OF CENTURIES NEAR END

Premier Car Maintains Daily Schedule of One Hundred Miles—Far Ahead in Its Total Mileage.

While the Premier century car, which Joseph Moore is driving, has not yet finished its one hundred days run of one hundred miles per day, it has nevertheless covered more than 10,800 miles, and when the driver pulled into Indianapolis this week, he and the car were given a rousing reception. About 20 local motorists met the car at Greenville, 25 miles out, and the Premier company tendered a chicken dinner to the man at the wheel and made the return joyous. The car's 10,000 mile mark was passed at Pittsburg, Pa., on August 24, but the one hundredth day will not be reached until September 8, making the total mileage by that time over 12,000 miles.

THE PREMIER "CENTURY PER DAY" CAR

The performance is a most interesting one, inasmuch as the motor is in excellent condition and shows no wear or noise, whatsoever. It is claimed that not one part of its equipment has been replaced since the run started. This automobile took part in the Glidden tour as an official press car and covered the entire distance over the half-dozen ranges of mountains running on schedule each day. At the close of the tour, it went direct to Boston and since then has been making its daily centuries in and between the various large cities.

Springfield to Abate Headlight Glare.

Mayor J. W. O'Brien, of Springfield, Mass., called a conference on Friday of last week to discuss the dangers incident to the use of glaring arc headlights on street cars. A body of 15, representing motorists' interests and superintendents of two street railways were present. On behalf of the Springfield automobilists, who have been complaining for some time of the dazzling headlights on trolleys, F. W. Bement read a long list of cities in which a plan for turning off street car lights or subduing them, was in force. The attitude of the railway representatives was that they were willing to try any feasible plan for doing away with the powerful arc lamps which would not endanger the safe operation of cars.

It was finally arranged that street cars shall be equipped with switches on the dashboard for the quick control of the headlight and that motormen shall be instructed to extinguish the light when a trolley meets an automobile or carriage in streets where the glare would confuse or endanger drivers. This idea, it is believed, will do away with one of the most annoying as well as dangerous features of night driving.

Legal Fight for Good Roads.

Aggressive methods for making officials look after the conditions of the roads for which they are responsible are being used by the Automobile Association of Scranton, Pa. Warrants have been sworn out by the organization for the arrest of the officials of Archbold borough on the charge of maintaining a nuisance in failing to keep the roads in repair.

For a Stage Line in Tennessee.

Col. I. Hill Dungan, of Humboldt, Tenn., who is described as a retired capitalist, is reported as forming a company to operate an automobile stage line from Humboldt to Dyersburg via Gibson Wells, a health resort.

RULES FOR EFFICIENCY CONTEST

Competition Restricted to Stock Cars Fully Equipped—Classification and Sub-Classification of Entrants.

The rules for the mechanical efficiency motor car test under the auspices of the New York Automobile Trade Association, which will take place September 16 and 17, restrict the competition to stock cars which must be fully equipped with bodies and seats, such as are shown in maker's catalog. No car will be considered completely equipped unless it appears as catalogued or in advance sheets, except top and glass front. Chassis must all carry stock touring or runabout body complete, including regular tonneau or rear seats, fenders, steps, running boards, lamps, horns, mats, etc. Extra tires may be carried, but no extra parts of the car or its mechanism, tools excepted, and no repairs or replacements of parts will be allowed except to the ignition system and its parts, though the driver and mechanic may make other mechanical roadside adjustments. Tire repairs and parts may be furnished by and carried on tire makers' supply cars, and tire makers' helpers may fit tires wholly or in part; but tire makers' cars must be regularly entered in the run in order to participate, as no cars of any kind will be permitted to participate unless regularly entered and numbered.

Before starting the entrants will be required to present their cars to the technical committee for examination, to determine whether or not conditions are complied with. The cars will be again examined by the committee at the finish of the run.

Where the car is driven with magneto, for which an extra charge is made, the amount will be added to the price of the car at the time of entry. Any manufacturer or agent entering a stock machine must agree to sell it at the entered price, and imported cars must be entered at their selling price in this country.

A liberal time schedule and time limit will be provided to suit the different classes and powers, but time lost for tire repairs will be allowed. Open controls and checking stations will also be maintained, with motorcycle couriers to observe and report any infractions of the rules.

The classification will be as follows:

Class A—Open to all cars selling for $850 or less.

Class B—Open to all cars selling for $851 to $1,250.

Class C—Open to all cars selling for $1,251 to $2,000.

Class D—Open to all cars selling for $2,001 to $3,000.

Class E—Open to all cars selling for $3,001 to $4,000.

Class F—Open to all cars selling for $4,001 and over.

Class G—Open to taximeter cabs carrying two passengers and driver.

All entries in these classes will be further subdivided by their passenger-carrying and load capacity; for instance, small runabouts carrying 2 passengers; small runabouts carrying 3 passengers; small runabouts carrying 4 passengers; touring cars carrying 5 passengers; touring cars carrying 7 passengers; touring runabouts carrying 2 passengers; touring runabouts carrying 3 passengers; touring runabouts carrying 4 passengers. Framed certificates will be awarded each successful trade entrant and bronze medals for the winning drivers in each class.

The route will embrace the whole of the south side of Long Island from Bay Ridge, its westerly end, to its easterly end at Montauk Point, and the return trip, crossing Long Island at Good Ground to Riverhead, taking in the whole of the North side. The program contemplates a midday clam bake at Capt. Bill Graham's Ye Anchorage Inn at Blue Point, L. I., and an entertainment with campfires, and a mammoth roast ox barbecue and band concert at night at Montauk Inn, besides a second-day noon luncheon stop at Riverhead.

Comet Shines at Santa Rosa Meet.

With clear skies, a smooth track and an enthusiastic crowd numbering 2,000, the race meet at Santa Rosa, Cal., on August 23d, was a big success. The feature event was the 25 miles free-for-all, won by Fred J. Wisedan, driving a Stoddard-Dayton, who finished in 29:44. The Comet, a San Jose made car, scored the fastest mile in 58 seconds. It won the class for cars under $1,500, covering the distance of ten miles in 11:05, although the Buick gave it a hard run for the money. These two cars finished in the same position in the five miles event for cars under $2,500, the former finishing in 5:41⅗ and the Buick in 5:44. The Comet had a big day as it also won the mile novelty in 1:55. A Stearns car secured the ten miles for cars listing over $2,500, with a White a close second, and a Peerless third. The 25 miles for motorcycles went to a Thor machine in 27:18.

Automobile Fire Engines to Compete.

What undoubtedly will be one of the most unique automobile races ever held, is scheduled to take place at Joplin, Mo., on September 8. It is to be an automobile fire engine contest—the first of its kind ever held in America. The fire wagons of the Robinson Fire Apparatus Co., of St. Louis, are to be pitted against cars manufactured by A. C. Webb, of Vincennes, Ind., late of Joplin, Mo. In addition to speed trials, these machines will be put through other competition tests. This will be at a tournament of firemen from five middle western States. Joplin claims to be a leading American city in respect to the use of motor fire engines. That city already has purchased three Webb cars.

NINE ENTRIES FOR LOWELL RACE

Three Foreign Machines Included—Noted Drivers Who Are to Compete—Very Fast Time Expected.

What undoubtedly will be the biggest of the Labor Day motoring events, is the Lowell (Mass.) 250 miles road race over a 10 miles course in the Merrimac valley, for which nine entries have been made. It bids fair to come up to the fullest expectations of the Lowell Automobile Club, as on account of the short course the contest committee limited the number of entries to 12 and there is a possibility of a full dozen cars starting. Of the nine already entered, three are foreign machines and six are American made. Two Isottas and a Fiat will represent Europe, the former being driven by Louis Strang and Al Poole, of Savannah and Briarcliffe fame, while George Robertson will handle the Fiat.

The American entries consist of two Knox cars, two Buicks, a Simplex and an American. One of the Knox cars will be piloted by Charles L. Bissell, a French driver who has driven abroad and at Ormond, while the other will be guided by either Albert Dennison or William Bourque, of Springfield. Robert Burman, who has seen a few 24 hour and track races, and C. S. Smith will drive the Buicks, while Frank Lescault will stick to the wheel of the Simplex and A. J. Andrews the American. Several of these drivers have been out in the chill gray dawn for practice trials the last few days and seem favorably impressed with the course. Louis Strang made the circuit for the first time on Saturday last and stated that he expects to be able to make between 80 and 90 miles an hour on the straight stretches of the course. Other more conservative drivers say that an average speed of 60 miles an hour will be about the maximum rate. The race is to start at 10 a. m., and the contestants will be sent away at one minute intervals, from which it will be seen that the last of the drivers will scarcely be started before the others commence to circuit past the grandstand.

Considerable time and money has been spent to oil the course and put it into shape and bank the turns, including the "hairpin" at Tyngsboro. A wire fence on each side of the road extends the entire length of the circuit to keep the foolish ones from getting under the wheels. The regular Lowell police force will patrol the turns and points liable to be congested and a large number of special police have been hired to take care of the balance of the course. The race is to be run rain or shine.

All roads crossing the course will be closed to public travel at 8 o'clock on the morning of the race, but the main course will be kept open until the time for starting the contests, which will be two hours

Digitized by Google

later. There will be telephone service with nine stations disposed along the course, so that in case of accidents it will be possible to signal from all points at once. The grandstands, with a seating capacity of 10,000, are situated three-quarters of a mile beyond where the finishing point of last year's race was, which will allow the spectators to view the race at a point where the contestants are expected to make 90 miles an hour. Back of the stand and close to the Merrimac river, there is a level space which will be reserved for the machines, drivers and mechanicians.

The National Association of American Automobile Engineers will attend the race in a body, and, according to President John O. Heinze of the Lowell Automobile Club, under whose auspices the races are being run, there will be at least 150 present.

New Route to the Water Gap.

Automobilists who have followed the circuitous route to Delaware Water Gap will be pleased to learn that the new Slate Hill-Greenville-Port Jervis State road leading to the Shawangunk mountain was opened to travel this week. It is the most expensive and best constructed road in Orange county with easy grades and smooth macadamized surfaces and passes through one of the most beautiful regions in the East. The road is nearly 13 miles in length and cost $137,000 to build. It is the most direct road into the Delaware Valley and will be the main road to Delaware Water Gap. The acceptance by the State has not been made, but the contractors now allow public travel over it so that by this route automobilists can make the run from Newburg, the eastern end of the county, to Port Jervis, the extreme west, entirely on State roads, except a short distance from Monroe to Chester. The route over the State is completed from Tuxedo to Port Jervis.

Oldfield Gives Kalamazoo a Show.

Before a crowd of 3,000 persons at Kalamazoo, Mich., on Sunday, August 30, Barney Oldfield, up to his old tricks again, "lowered his one mile record for Michigan tracks." He covered that distance in the fast time of 58¼ seconds and considering that the track at Recreation Park was in none too good condition, Oldfield's performance is noteworthy. His previous Michigan record was made at Detroit, when he reeled off a mile in 0:59⅕.

"Rubbernecks" for Sightseers in London.

American sight-seeing or "rubberneck" wagons have invaded London and are highly popular with the out of town visitors and with tourists from the United States. Their bulk makes them the object of spirited verbal attention from the London 'bus drivers, who have further ground for giving play to their caustic tongues because the motor wagons are taking away a considerable proportion of their sight-seeing and fee-giving patronage.

UTILIZING WORKMEN'S BRAINS

How Chalmers Encourages Employes to Give Thought to Their Work—Prizes for Available Suggestions.

Getting the benefit of his employes' brains as well as the work of their hands, always has been one of the business principles of Hugh Chalmers, president of the Chalmers-Detroit Motor Co.

In order to make it easy for his employes to give to the company their ideas about the work that they are doing, Mr. Chalmers has just inaugurated in the Detroit factory a suggestion system.

REGISTERING HIS SUGGESTION

Throughout the factory are placed small registers, such as are used in many stores for making duplicate copies of bills. The employes are invited to write on these registers any suggestions that they may wish to make regarding their own work or the work of any department, where they see a possibility of improvement.

The register makes three copies of each suggestion. One copy is retained by the employe, the second is dropped by him into a small metal box placed at the side of the register, and the third is locked up in the register for a permanent record. The suggestions in the boxes are collected at intervals and taken to the general manager's office, where they are given careful consideration. When investigating the suggestions to find out how valuable they are, the name of the suggestor is never given out, so that there is no possibility of creating a jealousy in the departments, or of allowing a foreman to think that some of his employes are complaining against his methods.

Prizes are offered for the best suggestions submitted. These prizes are awarded quarterly and are as follows:

First prize—$25 for the best suggestion adopted.

Second prize—$15 for the second best adopted.

Third prize—$10 for the third best adopted.

Fourth prize—$5 for the fourth best adopted.

In addition to these prizes, the sum of 50 cents is paid for every suggestion adopted, no matter whether it is good enough to win a prize or not.

This suggestion system has been welcomed by the employes, and the company receives every week a number of suggestions as to improvements in mechanical operations, improvements in methods of doing work in the factory, and improvements in office system.

Practical Test of Splash Guards.

Outside splash guards for protecting passersby from unpleasant spatterings of soft mud or puddle water are engaging so much attention from inventors across the Atlantic that means of testing the different devices offered, to determine their respective efficacy, have had to be devised. The most convincing method hit upon as yet is to have a man don a pure white duster and stand beside the path of a car as it plunges through a pool of mud and roadwater. The first trial is made without the splash guards, and the results of their omission are recorded in a photograph of the bespattered once-white garment worn by the victim at the roadside. The second trial finds the same man encompassed in another white duster like the first, and if the splash guards, which are this time mounted, are as good as they are intended to be, the subsequent photograph of the dust coat will show it spotless and unharmed.

Lost Power Caused by New Valve.

Marked loss of engine power sometimes follows the fitting of a new inlet valve where the latter is of the automatic type. Such a sequence of cause and effect generally indicates that the spring of the new valve is too stiff and should be eased up to correspond with the old adjustment. In the case of the fitting of a new exhaust valve, a diminution in the power probably has its cause in too weak a valve spring, allowing the exhaust valve to open slightly on the suction stroke.

Belgians Organize Automobile Express.

An express company has been organized in Antwerp, Belgium, with a capital of $300,000 to do a general express business in the city. The enterprise will be known under the title La Compagnie Generale Amersoise de Transports. The transportation of articles will be done entirely through the medium of motor vehicles.

HEAVY VEHICLE TIRE PROBLEMS

Michelin Discusses the Relative Merits of Solid and Pneumatic Construction—Deductions from Experiments.

It is generally admitted that pneumatic tires are unsuitable for use on commercial motor vehicles of the heavier type, because of the enormous strains which must be resisted and the absolute necessity of economy in upkeep. Just what considerations determine the boundary between economical use of the air tire and the enforced application of the solid substitute, however, probably few persons outside the tire industry itself are at all aware. In a paper recently read before the French Society of Civil Engineers the well-known tire manufacturer, M. Michelin, discussed the subject and offered some valuable suggestions on the proper design of tires for heavy commercial vehicles.

The pneumatic tire has hitherto been found useless for heavy weights, for two reasons—explains the Scientific American, in an abstract from this source. The largest pneumatic tire cannot safely carry more than 1,500 pounds and the pneumatic is inferior in economy, owing to a fact which many experiments have permitted M. Michelin to express in the following empirical law:

"The total travel of which a tire is capable is inversely proportional to the cube of the weight which it carries." For example: If the load is doubled the average wear and tear will be multiplied by eight, and an increase in weight of 5 per cent. will cause an increase in wear and tear of 15 per cent.

So, every attempt to increase the load has been followed by such rapid wear of the tires that their employment had to be abandoned.

Hence, it has been found necessary to retain the solid rubber tire in order to lessen noise and soften shock.

At present the situation of the heavy weight vehicle is precisely the position occupied by the touring car before the adoption of pneumatic tires. The vibrations and shocks transmitted to the chassis and to all the mechanism rapidly wear out the motor and gearing. Of 162 vehicles possessed by the Paris Autobus Co., not more than 97 are ever in service at once, although the repair and maintenance shops employ a force of 200 mechanics. Yet the oldest of the vehicles has been in service only eighteen months.

The problem of tires for heavy vehicles is therefore still unsolved. To prove how unsatisfactory is the solid rubber tire, M. Michelin cites the following experiment: A wheel was caused to rotate with the tire velocity of 15½ miles an hour while carrying a load of 1,100 pounds, and furnished alternately with a pneumatic and a solid rubber tire 2½ inches thick, which was in contact with the broad tire of another and larger wheel upon which different small obstacles could be fastened. The displacements of the hub of the small wheel were inscribed in their true dimensions by a style upon a rotating cylinder. Vibrations amounting to ¼ inch for the solid, but only 1-50 inch for the pneumatic were recorded, even when no obstacle was present. These vibrations are caused by a slight eccentricity of the large wheel. They give an idea of the inferiority of a solid tire, which is confirmed by the passage of the wheel over obstacles. The first obstacle was a semi-cylinder about ⅘ inch high. This produced an elevation of the wheel amounting to 0.16 inch with the pneumatic and 0.40 inch with the solid tire. In other words the pneumatic absorbs four-fifths and the solid tire only one-half of the obstacle. The difference increases with the size of the obstacle. On an elongated block ⅘ inch high, the rise was 0.36 inch with the pneumatic and 1.16 inches with the solid tire. A semi-cylinder 1.2 inches in height caused the wheel to rise 0.28 inch with the pneumatic, and 1.04 inches with the solid tire. Finally, with an elongated obstacle 1.2 inches high, the wheel rose 0.44 inch with the pneumatic and 2.36 inches with the solid tire. In every case the ascent of the wheel, carrying a pneumatic tire, is less than the height of the obstacle; while with the solid tire the ascent is always greater than the height of the obstacle, unless this is very small. In endeavoring to repeat the experiment with the solid tires, the steel axles of the two wheels, whose diameters were 1.8 and 2.4 inches, became sprung. In order to avoid breakage the manufacturers of heavy automobiles have been obliged to reinforce their axles. M. Michelin states that he has seen axles made of I bars of forged steel of a height of 9 inches. For heavy-weight articles Michelin recommends the multiple pneumatic. It may consist, according to the weight which it has to carry, of two or more pneumatics, placed side by side upon the same wheel. For heavy vehicles, we are not concerned with high speed, and the construction must be adapted to give great strength and supporting loads. The envelope of the multiple tire, therefore, would not be suited for a touring car. It might be feared that two or more tires exposed together to the inequalities of the road would wear out almost as soon as a single tire, but that is not the case. Twin tires are found at last from three to seven times as long as single tires.

This is chiefly due to the law which we have already quoted, but there are other reasons. The twin tire suffers less from the brakes because their pressure is distributed over double the surface. Seventy-two experiments have proved that, at the same pressure, a pneumatic of small diameter absorbs obstacles better than one of large diameter.

REGISTERING HEAT OF CYLINDER

Prof. Hopkinson Devises Apparatus to Give Direct Temperature Readings—Application of an Electrical Principle.

In the study of what takes place in the cylinder of a gasolene engine numerous satisfactory forms of apparatus have been devised for measuring the pressure at all stages of the cycle operation, but the matter of definitely registering the temperatures attained has presented more difficulty. A recent advance along this line, however, has been developed by Prof. Hopkinson, of Cambridge University, who has devoted a great deal of attention to the theory of explosion motors. His device is of much a character as to give direct temperature readings of the heat inside the cylinder. The principle of the apparatus is founded on the increase of the electrical resistance of copper with the increase of temperature.

For the purpose of his tests, Hopkinson has built a vertical cylinder of cast iron, 12 inches in height and diameter, the interior of which is lined wth wood and the top and bottom covered with cork. In the cylinder is introduced a helical ribbon of sheet copper about ¼ inch wide, with an air space of 1-25 inch between the turns. Coils of the copper ribbon are also placed at the top and bottom of the explosion chamber, forming part of the circuit with the helical coil on the sides. The increased resistance offered the passage of a current through the strips of copper during the period of an explosion provides data sufficient for an accurate calculation of the increase of temperature.

The principal circuit consists of a set of 50 accumulators, a group of lamps and the coil of copper ribbon. Shunting the cylinder coil is a second circuit which includes a galvanometer and a resistance. Again, a third circuit, connected to shunt the resistance, is introduced, it having 6 accumulator cells and a resistance of its own. The lamps and the resistances are so adjusted that a current of 8 amperes flows through the lamps, while no current goes through the galvanometer. The cylinder having been filled with an explosive gaseous mixture and the charge ignited, the heat generated causes a small increase of the electrical resistance in the cylinder coil of copper which produces a proportionate increase of the difference of potential of its poles and sends a current through the galvanometer proportional to these changes. The delicacy of the galvanometer is such as to render mechanical means of registering its action impracticable, so that its deflections are recorded by a beam of light reflected from a mirror on the end of the instrument's needle to a sheet of photographic paper.

In connection with a pressure gauge on

Digitized by Google

the top of the cylinder, which shows the pressure at each instant of the explosion, the temperature records give valuable information as to what occurs during the power stroke of a motor. Means for varying the compression under which the explosion takes place are provided in the apparatus, and the experiments which are being conducted will throw a great deal of light on many of the problems in gasolene engine practice.

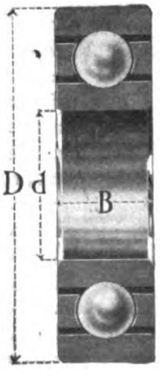
Novel Mounting of Copper Flanges.

Copper cooling flanges for air cooled motors have long offered a problem to designers and manufacturers in the matter of their application, the desideratum being to have the union of the copper with the iron as close and complete as possible in order that the conductivity of the copper in carrying away the heat from the cylinder may be assisted to the utmost. Elements of novelty are claimed by R. D. McAlvay, of Los Angeles, Cal., for a method of mounting the copper flanges which he has incorporated in a new car of his own design, which was built specially for use in the Western deserts.

The flanges, which are mounted vertically along the sides of the combustion chamber, are cast integrally with the gray iron cylinders, without, however, any melting of the copper. The copper plates or flanges do not penetrate to the interior wall of the cylinder, but have their bases imbedded sufficiently deep in the iron to give them all necessary security. The tops of the cylinders have no flanges, being flat and mounting the inlet and exhaust valves operated by overhead tappets. A further departure from standard practice is the placing of the valves fore and aft instead of at the sides of the cylinders, and the valves are so grouped on the four cylinders that the inlets in each pair are nearest each other, to equalize the manifold flow from the carburetter.

Emergency Remedy for Failing Clutch.

Nothing in connection with driving an automobile is more annoying to the operator than to have a clutch which fails to hold. When this condition exists various disagreeable features ensue; the motor races, the friction created between the clutch and its seat has a deteriorating effect on both parts and the car fails to respond to the action of the motor, which ofttimes places the vehicle and its occupants in a dangerous position. When this condition exists, if the connection is of the friction cone type, a simple temporary remedy lies in the use of Fuller's earth. The face of the leather clutch straps should be cleaned thoroughly with gasolene; then the straps should receive a liberal application of Fuller's earth and if the clutch seat has been carefully wiped until all oil and grease is removed, it will be found that the objectionable slipping has been reduced to the minimum or even entirely removed.



MORE BALLS IN THE BEARING

New Foreign Device Provides More Space in the Separator—Special Advantages That are Claimed.

Refinements in ball bearing construction continue to engage the manufacturers and the improvements along this line, while presenting no introductions of radically new principles, present evidence of the thought and care expended in giving recognized theoretical advantages and considerations a practical commercial and mechanical em-

bodiment. An instance of the sort is a new type of "silent" annular ball bearing, possessing some special advantages over preceding types by the same makers, has been produced by Fichtel & Sachs, of Schweinfurt, Germany, in which the distinctive feat-

ure is a separator so formed as to permit almost the entire space to be filled with balls. Having more than the usual number of balls for a given size, the bearing is claimed to effect a wider distribution of the load among several balls instead of concentrating it on three or two, or even on a single ball, as is said to be the case with some types of bearing.

The separator is die cast, of a special alloy. As shown by the accompanying illustrations, it is split in the central plane of the balls, and the two halves are united by brass wires of dovetail section, which are inserted in dovetail shaped grooves and have their ends clinched over into notches in the sides of the separator. The reduction of the number of balls used, as compared with the "full" type of bearing, is with this separator only one ball.

The method of introducing the balls resembles that used in former types of the F-S bearings, as imported by the J. S. Bretz Co., of New York, being distinguished by the use of angular entering grooves in the sides of the inner and outer races. Contrary to a more or less general impression, these side grooves are not quite so deep as the races themselves, so that after the bearing is half filled the remaining balls are sprung in under some pressure. Once in, they would be prevented from any tendency to escape by the angularity of the grooves.

This construction presents obvious advantages over that in which the races are so shallow that the balls may be sprung in from any point, as the latter are frequently too springy to endure severe end load. The deep ball races and the use of a greater number of balls which the side groove method of introduction and the new type of separator permit, result in a capacity for carrying loads of from 1-10 to ¼ of the radial load capacity. The makers of the bearing lay special stress on the high quality of the materials used and the extreme accuracy of the workmanship and sizing, since to realize the advantages of this type in actual practice perfect uniformity of the size of the balls and exactitude in the formation of the races is manifestly necessary.

Improving Methods of Heating.

In the design of heaters for cold weather use, which give promise of great popularity this fall, as numbers of private owners are preparing to install them, it is to be remembered that if the exhaust from the motor is used it will have a very unpleasant sound if piped directly into coils or chambers placed in the flooring of closed bodies. Town cars and limousines thus equipped have been found to be very disagreeable in this respect, the pulsations of the exhaust having a magnified effect that not only makes conversation difficult but is extremely wearing on the nerves. This objection has been circumvented in some cases by the installation of a separate hot water circulation system, taking its heat from the jacketing of the exhaust on water coil underneath the body. Another method, where consideration for the comfort of the passengers outweighs the slight loss of engine efficiency involved, is to conduct the exhaust through inside coils of generous pipe diameter after it comes from the muffler. In this method, the muffler itself is enclosed in a receiving chamber for the exhaust gas, the chamber serving as an equalizer, after which the hot gas finds its way in a fairly steady flow through the coils of the interior heater and out through a lead of pipe underneath the car to the open air.

MOUNTING THE CONE CLUTCH

Proper Method for Safeguarding Against the Effects of Disalignment—Details in the Work of Assemblage.

One fruitful cause of dissatisfaction with the otherwise satisfactory cone clutch has been that with certain of the more common methods of mounting, any possible distorsion of the clutch shaft, springing of the cone itself, or disalignment of the clutch and crank shafts, would cause it to engage unevenly, causing jerky starting action, dragging and "spinning" when out of engagement, and generally imperfect action. In the method of mounting the cone, then, rests the chief problem in the design of this type of clutch. As was indicated in the Motor World's announcement of the specifications of the 1909 Pope-Hartford car, last week, the design of the new clutch contains elements of general interest. That these relate more particularly to the method of assemblage and the way in which the device is safeguarded against the effects of disalignment a study of its details will show.

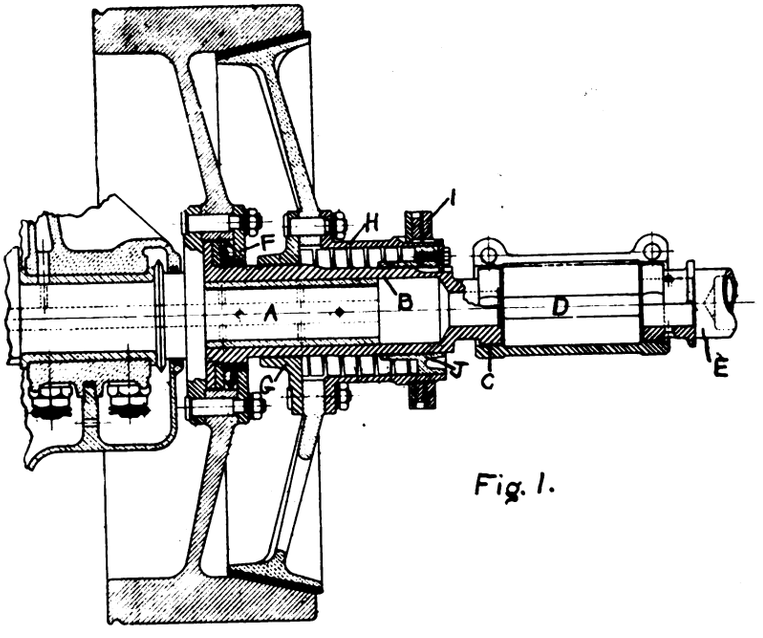

Fig. 1.

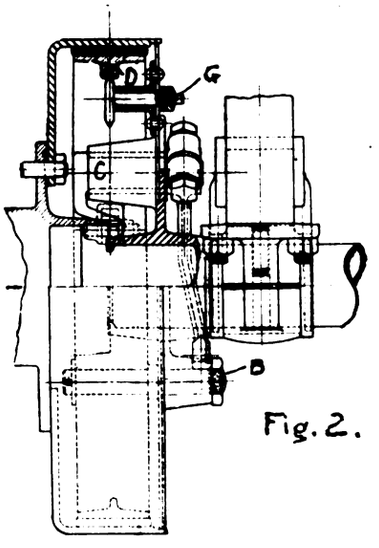
As is indicated in the accompanying illustration, Fig. 1, the principle bearing of the clutch on an extension of the crank shaft, A, is very long. The hollow clutch shaft, B, which immediately surrounds it, a bushing being supplied to guard against abrasion, has the advantage of being given only a rotary motion, the longitudinal movement of engagement being entirely independent of this member. At its rear end it is necked down and formed into a square shoulder, C, which engages the squared hollow sleeve, D, into the opposite end of which is fitted a corresponding member in the transmission shaft, E. The sleeve being split along one side and fitted with shims, it is possible to take up any wear which results from the working of the universal joint thus formed, by means of the bolts which clamp it together at either end.

The forward end of the shaft, B, is flanged outwardly and butts against the face of the flange upon which the fly wheel is mounted, a free washer and ball thrust bearing being interposed between its forward face and the collar, F, which is fastened to the fly wheel by through bolts. By this means the clutch shaft is held in positive relation to the crank shaft, its alignment being preserved by its great length of bearing surface and its end thrust being taken up by a plain bearing on the one hand, and a ball bearing on the other. Up to this point the device is lubricated directly from the crank case—an important point to note. A duct leading through the rear journal of the shaft is tapped at one point to register at every turn with the oil feed to the bearing. By this means oil is carried through other ducts to the bearing surface by centrifugal force.



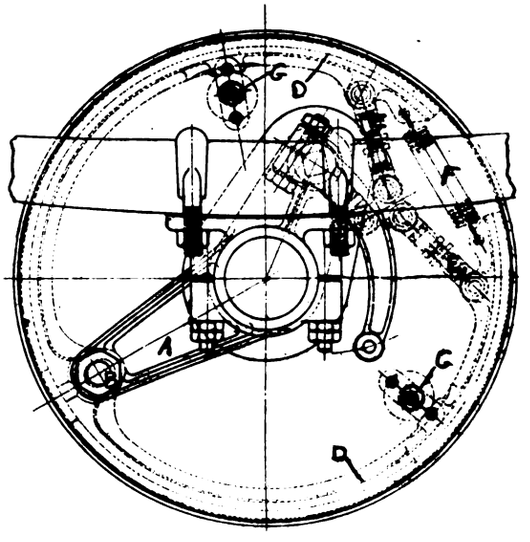


Fig. 2.

The outer side of the sleeve, B, is squared and on it is mounted the boss, G, upon which the cone disc driving member is bolted. Upon the back side of the driving cone is bolted the sleeve, H, the rear end of which carries the adjustable collar, I, which is employed in disengaging the device. Within the sleeve, and threaded on the clutch shaft is the nut, J, suitably locked in position. Between this nut and the rear face of the boss, G, is the engaging spring, which takes its thrust from the clutch shaft itself, the stress being taken up by the ball bearing already noted. It will be observed that the cone group always rotates with the clutch shaft, and is given only longitudinal motion with relation to it The double movement which is necessary in any clutch —that is to say, the rotary movement with relation to the crank shaft which occurs during release, and the longitudinal movement which occurs at the moment of release or engagement—are thus segregated and is carried on independent bearing surfaces.

In addition to these precautions against disalignment another and still more radical feature of the same sort is found in the method of actuation. Instead of a plain yoke to engage the collar, I, two independent arms are used. The pedal connection to these arms is by means of a linkage terminating in a short balance beam each end of which is connected to one of the arms, while the pull of the pedal is applied at the center. By this means the drag on the flange is absolutely equalized, and even should the pedal rocker shaft be out of alignment with the motor, the clutch would still be drawn out in a straight line, and would not tend to "cock up" and drag on one side.

Another new feature of the same machine, which also is noteworthy, is the method of

Digitized by Google

adjusting the emergency brakes, which is unusually generous in its application. As shown in Fig. 2, the mechanism, which is of the expanding type, is actuated by a toggle arrangement instead of the more conventional cam movement. The spider, A, which is rigidly attached to the axle tube carries upon one of its arms the anchor bolt, B, and upon the other the actuating rocker shaft, C, which projects through the cover plate. The spring seat being loosely mounted on the tube, it follows that the torque of the brakes is taken up entirely by the same member, which receives the torsional driving stresses and which was described in detail in the previous article already mentioned.

The brake shoes, D-D, are expanded by means of the toggles, E-E, worked by a triangular link connected with the internal rocker arm of the shaft, C. In contrast to the ordinary system of cam expansion, this arrangement provides adjustment in each of the toggle members, and makes it possible to adjust for unequal wear on the two shoes, should this occur, also providing for a nicety of adjustment which is not found where the entire regulation must be done in the drag rods outside the brake. The shoes are normally held in the off position by means of the spring, F, which draws them against the two stops, G-G.

Another adjustable feature is here introduced in the design of the stops, which are in the form of circular discs eccentrically mounted on short studs projecting through the sides of the cover plate and locked in position. A slight rotation of the studs permits the bearance of the shoes to be regulated so that exactly the same amount of movement always will be required to throw them into engagement. The utility of this provision, when coupled with the adjustability of the individual toggles, will be at once apparent.

Still another point which should be mentioned is the method of mounting the drums. Instead of being attached to the hub flanges, as is commonly the case, the brake drum is mounted on the hub itself, the latter extending inwardly as far as the center line of the brake shoes to give good support for the wheel and brake. By this means less strain is brought to bear on the hub bolts than with the more common arrangement, and the wheel is less liable to work loose in consequence.

Loose Check Nuts Invite Trouble.

Loose check nuts on the connecting rods in the braking system may become the cause of a serious mishap if not taken up in season. When the check is removed from the turnbuckle or other adjustment which it is supposed to guard, the tendency of the vibration is to loosen the adjustment of the bands. As this may ocur while the machine is running, the possibility of having the brakes fail owing to slack adjustment and without any previous warning, is well worth considering.

THE SECRET OF GOOD SURFACING

Essential Value of a Liberally Built Foundation—Suggestions for Effective Laying on of Primary Coats.

With the advent of the automobile there has come a demand for the best sort of surfacing, and, for the most part, nothing short of this will apparently suffice.

The ordinary processes which have obtained outside the strictly high grade city custom shops are inadequate to meet the demand for the more excellent surfacing necessary to produce in the wide-reaching automobile a work of art. And this surface, it has been further demonstrated, cannot be built up on an impoverished foundation of primary coats, whipped together by the doctors of the old school of surface magic, says the Carriage Monthly. The foundation must be liberal, and composed of the best sinew and substance put together by the manufacturer. And coming to the part, foremost among all, which the painter plays in this surface making practice, we find that a good quota of coats must be used. Above the primer, confining our attention now to body surfaces, should come at least a couple of strong, supple coats of lead, perfectly laid, to be followed by at least five coats of roughstuff. Upon metal surfaces which have many uneven places in them, it will even be found necessary to apply a greater number of coats in order that in rubbing the roughstuff a perfectly level surface may be secured without cutting the higher parts dangerously close in order to reach the naturally lower ones.

However, we incline to the belief that upon all metal surfaces, which through processes of construction, show dents and depressions, markedly along the line where the panels are attached to the frame work with pins, draw puttying should be resorted to over all existing shallow places. The work of reaching the proper surface both in point of quality and of levelness is thereby rendered very much easier.

The sum of the whole matter of surfacing with roughstuff consists in getting together such a substantial body of pigment that the surfacing down to an absolutely level and smooth plane may be done without cutting any part of the foundation dangerously close to the basic structure beneath.

And where this is accomplished we deny the need of any 'stopper" or other coat being interposed between the body of roughstuff and the color coats. Technically, the "stopper coat" was designed to impart to the rubbed surface of roughstuff an impalpably fine, intact, close-grained film, through the medium of which the coats to come after were to be absorbed in no essential degree, thus sustaining them in the full strength of their power entirely above the primary foundation.

Nevertheless, latter day foundation building, as expounded and demonstrated by the leading members of the craft, has proven the undisputed lack of necessity of any "stopper" coat above the roughstuff. Certainly it is true, and is capable of proof along any of the avenues of American cities of the first class, that present day automobile and carriage finishing is the equal of, if not superior to, the finishing of previous times.

The massive contour and sweep of automobile surfaces naturally exact a fairly minute attention to every least detail of surfacing. Not long since the writer, in touring a certain large auto paint shop, had his attention called to a workman engaged in putting roughstuff upon touring car bodies. The coarse pigment on some bodies was being laid off with horizontal brush strokes, on others with vertical strokes, and on still others with angle strokes. He was advised that the direction of these angle brushings was reversed in regular order, and by their employment, along with the horizontal and vertical strokes, the filling pigment was brushed in four different directions, thus giving a foundation of the closest possible texture, more compact, and with a more uniformly distributed flow of pigment. In similar manner the lead coats leading up to the foundation of roughstuff are, in the above shop, laid at right angles one with another, the reverse coat scheme being in this way carried through from primer to the guide coat atop the roughstuff.

Superior skill, and the diligence of Jacob of old, are, in the final review, the chief part and parcel of all the issues reverted to above in the enforced reign of fine automobile surfacing.

Effect of Speed on Fuel Consumption.

Experiments relating to the effect of speed on fuel consumption constitute a favorite pastime of many investigators at present, and although it has long ago been shown that the rate of fuel consumption per mile is materially increased with increases in the speed, the particular effects obtained with different sizes and types of motors affords the opportunity for each experimenter to obtain data which is of value as a contribution to the whole subject. Recent tests of this character have been tried with a six cylinder Italian Napier of 40 horsepower, the car being fitted with a measuring tank having a calibrated float rod so that the contents of the tank could be seen at a glance from the driver's seat. Four tests were made at as nearly constant a speed as possible over a selected stretch of road about 7¼ miles in length. The average speed maintained for each of the four tests was 19.2 miles per hour, 27.8 miles, 37.8 miles and 43.6 miles per hour, respectively, and the corresponding fuel consumption figures worked out at 19.95 miles, 16.26 miles, 14.2 miles and 12.9 miles per gallon, respectively.

TO SETTLE THE QUESTION FOREVER

Chicago Magazine Editor Will Decide Which is Best Car and Tire—He's a Philanthropist, He is.

No prospective buyer of an automobile need worry after October, as regards what make of automobile is the best, for that momentous question is to be decided definitely beyond all shade of doubt by a little heard of Chicago monthly magazine, which gives "advice to investors," and prints other such stuff. Not only will this magazine decide which is the best make of motor car, but also the best make of tires and speedometers. These three articles are definitely specified. The spark plugs, gasolene and lubricating oils probably will be settled later.

The editor of this Chicago publication apparently is bulging with benevolence. His scheme of determining the most meritorious product is to be so "legitimate" that he absolutely refuses to accept any advertising contracts from any manufacturer! This is "so that there can be no question of influence in the decision." The publishers, however, very graciously will condescend to furnish the manufacturer whose product makes the best showing, with all the extra copies of the magazine he may require—at a certain cost, of course.

In a letter which the Chicago editor has sent to numerous manufacturers, he says: "There is no question that the final decisions will mean a tremendous advertisement for the best car and accessories and a number of manufacturers have already assured us that they will use extra copies should their product show the best." Then follows a long list of cars and tires "being considered."

Just how the editor-gent expects to reach the important decision, which will settle the perplexing problem for the pee-pul, is interesting. He has spared no expense to send representatives to New York, Philadelphia, Baltimore, Washington, San Francisco, Keokuk, Frozen Dog, Ariz., and elsewhere for the purpose of "gathering data." When the data is all gathered, it will be carefully compiled and the editor then will decide the fateful issue. Buy the October number! The milk in the cocoanut is contained in the "extra copies." The "extra copy" scheme is a well ripened one.

Where Motoring is Discouraged by Law.

In contradistinction to the law of New York State which holds that an owner of an automobile is not responsible for damage done by his car when it is not being operated under his orders, is the law of Austria, which holds that there is no limit to the amount of compensation which may be exacted from a motorist for damage caused by his car. In Germany the damage limit is fixed at $12,500, but in Austria any sum may be collected, and in view of the notorious hostility of certain districts to motorists, a fortune might easily be lost on a single trip.

The secretary of the Vienna Automobile Club says that the position of motorists will be most serious if the law is rigorously enforced. Dr. Emil Frischauer, a Vienna lawyer, who has studied the measure, in commenting on its provisions said, "there is but one avenue of escape open to the motorist, and that is to evade the law by the formation of limited companies.

"Several motorists will join to form a company, each subscribing a certain sum, say, $5,000. A company with five members will thus have $25,000 at its command, and will purchase the cars of the five members, giving $5,000 for each. The company now becomes liable for all damage done by all the cars, and, being a limited liability concern, it is only able to pay fines or compensation to the limit of the funds in hand. Then it becomes bankrupt. Dr. Frischauer considers that such a company would be in a chronic state of bankruptcy, but this would be the only way of evading the law."

The Anti-A. A. A. "Secret" is Out!

At last the "secret" is out! One of the earliest and most confirmed and persistent of the race promoting press agent and "auto editor" critics, who has a few personal grievances of his own, finally has pointed out what he describes as "the sore and weak point" of th A. A. A. It consists of the fact that club representation being the basis of A. A. A. government, a few active members in each club are able to influence the election of the club delegates; It is as clear as mud, therefore, that the A. A. A. should be rent asunder and hanged to a lamppost for permitting such a dreadful state of affairs. But it will be a capital idea if the critics will now point out a club of any sort in which this is not always the case and also indicate how any national organization can alter such a state of affairs in any club while men remain human.

New York "Outlaws" Play the Usual Trick.

As is usual in movement of the sort, in their efforts to bolster up their very lame cause and to attract a gate to their 24 hours race at Brighton Beach next week, New York's little "outlaw" Motor Racing Association, which has become a corporation, has been making free use of a number of respected names. They gave out that Charles Jerome Edwards, president of the Long Island Automobile Club, would act as referee of the outlaw affair and that among the judges would be Charles J. Swain, of the Quaker City Automobile Club. As soon as the news reached those gentlemen they lost no time in repudiating and condemning the unauthorized use of their names, and in expressing their opinion of the attempt to connect them with the "wild cat" money making scheme.

ENDURANCE RUN, FAMILY STYLE

California Manufacturer Proves that It is Possible to Interest the Private Owners—Run Covered 1,100 Miles.

As a demonstration that private owners can be persuaded to take part in long tours or endurance contests when the schedule is arranged with a consideration for human comfort and not merely to break down the scores of manufacturers' teams in competition, the 1,100 miles "Tour of the Tourists," which ended at Los Angeles, Cal., on Saturday, the 22d ult., affords a conspicuous illustration. One of the features of the tour was that it was participated in not only by hardy road drivers of the do-or-die type, but the wives and children of the entrants were conspicuously present.

Mild rivalry, sufficient to add interest to the proceedings, was provided by a system for awarding perfect scores to those cars which arrived at all controls on time, but the itinerary and time allotment for each day was generous and the cars being all of one make, the Tourist, the competition for perfect scores was purely one of careful driving.

The entire trip consumed 10 days, the start being made from Los Angeles with 32 cars in the line. As the caravan made its way up the coast to San Francisco, more machines joined in at different points, so that the arrival at the latter city found the tourists about 50 strong. The charms of San Francisco were such that when the return to Los Angeles was scheduled only 21 of the full distance tourists returned, 12 of them making perfect scores.

Connecticut Warns Rhode Islanders.

Warning Rhode Island motorists not to kill the goose that laid the gilt-edged egg, Secretary G. K. Dustin of the Connecticut Automobile Club, has written a letter to the members of the Rhode Island Automobile Club, regarding motoring across the State border. It reads as follows:

"We have had our attention drawn to the fact that a great many cars outside of Connecticut are passing through here at a rate of speed very much above the legal limits, with the mistaken idea that our law allows them unusual privileges in the matter of speed.

"There is no question but that Connecticut at the present time has a very liberal law concerning motor vehicles. It is the desire of all Connecticut motorists and, I am sure, of all motorists, to maintain the privileges we now enjoy, rather than have them removed by some future legislature.

"With that end in view I am asking you to warn your club members with regard to excesses on Connecticut roads, and to urge them to drive in a careful and orderly manner while in Connecticut."

Standard Detachable Rim

Resolution passed by the NATIONAL ASSOCIATION AUTOMOBILE MANUFACTURERS at a meeting held in New York, August 5th, 1908.

"Whereas, the Standard Universal Rim, described in the report of "the Special Rim Committee, has been recommended by the committee "as mechanically satisfactory, be it

"RESOLVED that this association hereby adopts the rim so de- "scribed as standard, subject to the consummation by the Special Rim "Committee of satisfactory commercial arrangements with the patentee "and manufacturers."

At the above meeting all the detachable rims now on the market as well as proposed new rims were carefully considered.

TOO MUCH TO THE RADIATOR

The Lower Portion Useless is the Radical Conclusion of Two Foreign Experimenters—Results of Their Tests.

That the lower half of most radiators could be cut off and thrown away without impairing the engine running and that present radiator practice is very crude as compared with the scientific forms of fans and heat conducting methods that are available to motor car manufacturers are among the many radical conclusions arrived at by two disinterested experimenters, who in connection with studies of other motor car problems have been conducting a series of investigations into the big subject of radiator efficiency. The investigators are Dr. W. R. Ormandy and J. H. Lester, and the very interesting results of their laboratory proddings into the matter of engine cooling are given in the London Autocar. The attempts at tests were confined to radiators and were not extended to any complete test of the fan-pump-radiator system as a whole.

A distinct prediliction for the thermo-syphon system over the pump system exists with the experimenters by reason of the fact that their investigations show that the thermo-syphon system allows of the cylinders being warmed up to maximum efficiency temperature more quickly than with the pump system, the thermo-syphon system acting as a thermostat to maintain the temperature between narrow limits under widely divergent conditions of fuel consumption and speed. In the thermo-syphon system, the investigators maintain, the cylinder walls rapidly attain the temperature of maximum efficiency because not until this temperature is approached will there be sufficient hydrostatic head to cause that circulation which will bring a fresh bulk of cold water in contact with the walls. The rate of movement for the water is thus automatically regulated by the speed at which this temperature of efficiency is attained.

It is well known that certain portions of the cylinder tend to attain a higher themperature than the remainder and under the thermo-syphon method these portions of the cylinder are more rapidly reduced in temperature than the remainder owing to the increased velocity of circulation at these points. In the pump system, the experimenters declare, though the amount of water caused to pass through a cylinder casing may be vastly in excess of that passing in the case of a thermo-syphon system, it is possible to have strong local overheating, as the path of the water is conditioned by purely mechanical considerations, pockets and areas of comparative quiescence being of frequent occurence.

With a powerful pump and a good fan the temperature of the water when the engine is running on light load may never approach the temperature of maximum efficiency, and a pump system with its various parts so regulated that under ordinary conditions the maximum efficiency temperature would be attained, would be extremely liable to over heating under the less usual conditions of maximum load at low velocity.

In the experiments a honeycomb type of thermo-syphon radiator with fan was used, the total surface approximating 43 square feet, the front surface of the tubes being about 17 inches by 15 inches. This was mounted in connection with a 4x4¼ inch, two cylinder engine rated at 12.6 horsepower. The temperature of the radiator was obtained by inserting the bulb of a thermometer into the water entering at the top, while for ascertaining the temperature at the bottom the bulb was plugged into one of the lower air tubes. The rate of flow of the circulating water was ascertained from the gauge pressure set up in a glass tube with its open end facing the current of water entering the radiator, afterwards producing the same pressure from an external water supply and measuring the rate of flow into a gallon measure, the conditions as to levels being the same.

The principal observations were as follows: Temperature of water entering the radiator, 164 degrees Fahr.; temperature of water leaving radiator, 90 degrees Fahr.; rate of water circulation about 33 gallons per hour, or 110 seconds per gallon. Different conditions of running the engine, from light work in the experimental shed to heavy road work, showed little difference in these figures. It is assumed in the experiments that a cylinder temperature of about 160 degrees allows the maximum of power to be developed where the carburetter action is sufficiently perfect to introduce the charge in the form of a gas while a slightly higher heat is desirable where the fuel and the air enter the cylinder merely in the state of a mechanical division.

During the run of one of the tests, a period of about 25 minutes, the temperature of the radiator was observed at a point about half way down, and was found to be only 112 degrees Fahr. A comparison of the three temperatures, 164 degrees, 112 degrees and 90 degrees made it evident that the cooling effect was far greater at the top than at the bottom. This and other phenomena that were developed have brought the investigators to the conviction that the ideal design, however clumsy it might appear, would take the approximate form of a triangle with one side uppermost. Such a form, it is contended, in addition to taking advantage of the greater cooling efficiency at the top of the radiator near or at the water level, provides the best natural circulation, for it will give the greatest possible vertical head of relatively cold water in the radiator. It is asserted that such a form would permit of a construction much smaller and lighter than the usual types, for the same efficiency.

Among other improvements which the experiments suggest as practicable are the use of the sirocco type fan, which is in many respects more efficient than the conventional type. Its construction is that of a number of narrow blades arranged in cylindrical form parallel to the axis of rotation, like the bars of a squirrel cage wheel. The air enters at one or both the ends of the cylinder and is drawn out at the sides. Furthermore, radiators could be vastly improved, the experimenters believe, if instead of the air being brought through the radiators horizontally, as at present, it were introduced at the bottom and forced upward among the cooling plates or tubes, so that it would be coldest at the bottom.

Possibilities for the application of the Perkin tube system, a recent scientific development for conveying or conducting heat, are set forth as presenting food for thought. The system depends upon the evaporation of liquid from the lower end of a vertical or inclined tube or tubes sealed at both ends, the lower part of the tube being exposed to the heat and the upper to the cooling influences. The transfer of the heat from one end of the tube to the other is effected by the abstraction of the heat from the lower walls of the tube when the contained liquid is evaporated, and the dissipation of the heat as condensation takes place on the internal surface of the upper part, the condensed liquid running down to be again evaporated. Its use for cooling cylinder jackets might either be direct application to the cylinders or in connection with a special form of radiator. A suitable liquid and pressure in the tubes would make it possible to prevent any appreciable cooling effect until the temperature of maximum efficiency was reached.

In the course of other considerations in connection with cooling systems it is asserted that with the ordinary type of pumps it is almost impossible to prevent the introduction of grease into the circulating water. For the most part this grease is of a mineral origin and consequently of a non-saponifiable nature. This renders the task of removing the greasy film from the surface of the cooling area very difficult, because, unlike vegetable oils, mineral oils are not converted into soaps soluble in water by the action of caustic alkalies. From this, it is argued, it is wiser to use tallow or similar grease for the lubrication of the pump spindle, so that from time to time the water system can be thoroughly cleaned out by means of alkaline solutions. The remarkable influence exerted by even a microscopical thin film of grease in preventing the passage of heat through metal surfaces is well known to those who have studied the subject of economical steam raising but is little understood by most people. The decreasing efficiency which afflicts many pump cooling systems after the lapse of a few months' running is in many instances due to the formation of an oil film in the water jackets of the cylinders.

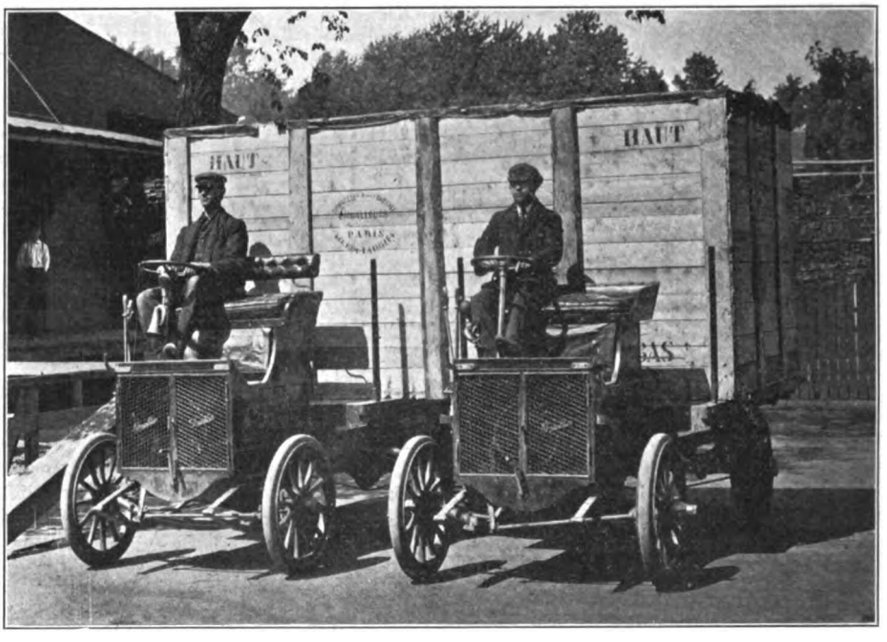
PUBLIC GASOLENE SUPPLY TANKS

As Necessary as Drinking Troughs for Horses, Farson Tells Chicago Horsemen—The Idea Catching on.

Thirsty automobiles that want water or gasolene should have street fountains for their accomodation just as horses do, according to John Farson, the Chicago motorist who has been prominent in automobile club and legislative matters, and so strongly does Farson believe this to be the case that he almost broke up a meeting of the directors of the Oak Park horse show by urging that a part of the horse show surplus funds be used in erecting his proposed gasolene tanks. In fact the staid directors of the horse show fund almost fell over with surprise and indignation when the real significance of Farson's suggestion penetrated their full consciousness, and there was a torrent of acrid and heated remarks concerning the propriety of an association for horse uplift rendering such Quixotic service to suffering motor cars. But when Farson looked the directors over and pointed out that practically every one of them uses an automobile instead of horses, he was able to get a better hearing for his proposal.

It had been decided by the horse show directors to divide the profits of the last show into four portions, each of which was to be devoted to a public purpose. Three of these had been disposed of when the disposition of the fourth came up for discussion. When the difficulty of selecting a suitable method of disbursing it was encountered, Farson made his suggestion of gasolene tanks, and after the first excitement was over, succeeded in bringing many of the directors to his way of thinking, and it is not improbable that the money will be spent in Oak Park to erect the stations.



"If these tanks for the use of automobilists would be good for Oak Park," said Farson, in explaining that his idea had a wider application, "there is no reason why they should not prevail all over Chicago. We have municipal watering troughs for our thirsty horses—why not municipal gasolene tanks for automobiles? Such tanks would not only be a convenience, but a positive step in advance for the city and its suburbs."

No Automobiles in Meade County.

In contrast to other localities which are claiming the largest proportion of automobiles in relation to population, Meade county, in South Dakota, claims distinction by reason of not having an automobile owned within its borders. This circumstance is not due to any prevailing indigence, but to the fact that all motor car agencies are far away and the residents with money have not had their thoughts turned toward automobile purchase. The recent passage of several machines through the county, however, has started a local movement for a prize to the first man within the lines who will buy a car.

Working Motor Trucks in a Team.

"Some things can be done as well as others," is a saying attributed to Sam Patch, an old time celebrity, and it is strikingly verified in the accompanying picture. The driver of either of the pair of Franklin motor trucks might well have exclaimed "That's the limit!" when brought up against the proposition to move the huge package of freight shown therein. But "where there's a will there's a way," and the way evidently was found. It is apparent that two motor trucks could not be employed tandem fashion, as may be done with some of the horse drawn vehicles, so the big box was loaded upon the two trucks placed abreast. Then all that was necessary was for the drivers to co-operate with care in the manipulation of the wheel and the regulation of speed.

FRANKLIN MOTOR TRUCKS "TEAMING"

Highland Park Will Permit Banners.

In spite of the failure of the legal committee of the local automobile club to get permission to string banners or warning signs urging motorists to beware of the speed laws, Judge Housell, of Highland Park, N. J., later changed his mind and has notified the club that it may hang a warning. So radical has been his conversation to the value of the club's idea that he says he will put up the banner at his own expense if the club does not provide one.

In Indianapolis, Ind., nearly all the wholesale paper manufacturers employ motor trucks to carry their product to the freight yards. The power vehicles have proven more practical than those drawn by horses.

NO DAMAGES FOR SPOILED ATTIRE

State Disclaims Liability for Spatterings from Oil Dressed Roads—Massachusetts Attorney-General's Opinion.

In answer to a request from the highway commission of Massachusetts, the Attorney-General of the State has rendered an opinion on the subject of the State's liability for damages caused to wearing apparel which has been spattered by oil on oil dressed roads. The Attorney-General holds that as there is no law to cover the subject, there can be no liability on the part of the State. He is of the opinion that the statute limits the recovery of damages to "want of repair" and to "defects in the highway." He held that the application of tar or oil does not constitute a "want of repair" and the term "defect" is not defined in the statutes. Continuing, the Attorney-General says:

"In order to constitute a defect within the meaning of the statute it is necessary that there should be something in the condition of the highway, either by reason of its construction or want of repair or in the nature of an obstruction, which is dangerous to the safty of the traveler and not merely damaging to appearance of his attire or the conveyance in which he travels."

In relation to cases where there were signs showing that the road was under repair the Attorney-General holds that the only inconvenience occasioned was the necessity of seeking another route. He holds that even if the application of the oil was improper or negligent on the part of the contractor or the agent of the Commonwealth it would not constitute a defect in the highway.

ANTI-SMOKE ORDINANCE STANDS

New York Park Board Sustained by Supreme Court Justice Dugro—Unqualified Decision in Test Case.

It is likely that the New York City park ordinance excluding smoking automobiles from Central Park and other parks will stand for a while, at least. Judge Dugro in a special term of the Supreme Court on Monday dismissed the writ of habeas corpus procured last Thursday in favor of William C. Tupper, a taxicab driver in the employ of the New York Taxicab Company, who was arrested on the charge of driving a smoking automobile in Central Park. The Court said that in his opinion the Park Board had not exceeded its general police power in passing such an ordinance and that it was not for the Court to determine whether or not the requirements of the ordinance were reasonable.

The New York Taxicab Co. sought to make a test case of Tupper's arrest and got out a habeas corpus writ before he had been arraigned in police court. Tupper was arrested while driving a taxicab containing Joseph H. Higgins, general superintendent of the company, and J. B. Kerr, counsel for the taxicab company.

Kerr tried to convince Justice Dugro that Park Commissioner Smith had exceeded his legal powers in making such an ordinance. The judge, however, said that the Park Board was in a better position than the court to determine what was a reasonable ordinance and what was proper for the regulation of the parks. Kerr contended that the ordinance was unreasonable; that it was too indefinite and did not impose any punishment for its violation. He said that it merely directed that smoking automobiles and cabs should not be used in the park.

Assistant Corporation Counsel George P. Nicholson insisted that the ordinance was a legal and proper one, and that having been duly filed, it carried with it the penalty provided for such ordinances provided by the city charter.

Justice Dugro overruled all the objections urged against the ordinance by Tupper's counsel.

"Who is to determine whether the ordinance has been violated?" inquired Lawyer Kerr when he heard the Court's ruling.

"Why, the police officer," replied the court.

Kerr remarked that it was placing a great power in the hands of the police, when the judge interjected:

"It is the same power that the police exercise and have to exercise in every case where a law or an ordinance is violated."

Justice Dugro then remanded Tupper to the jurisdiction of Magistrate Harris, who was sitting in Yorkville court, and who promptly fined Tupper $1.

"But, your honor," complained Tupper, who was sideflanked by his lawyer and employer, "no gasolene car can be driven without emitting some vapor."

"Then let them keep out of the parks," was the magistrate's advice as he called the next case.

The fine was paid, but there was some talk of an appeal.

Ducking Automobilists to Check Speed.

Out in Kansas a man by the name of D. A. Harrington recently devised a plan of his own to stop automobile speeding past his home. His scheme was an ingenious one and would have done credit to almost any small boy, for it consisted merely in squirting a garden hose at cars as they whisked by. Harrington had a whole bushel of fun, playing the stream of sparkling water on the many unsuspecting motorists and laughing with great joy every time he landed a good bull'seye shot and soaked a few people. Harrington calculated that automobilists would soon cease to drive past his Kansas City home, but this was an error of judgment, for the State of Kansas is now attempting to prosecute him on a charge of assault. For H. M. Beers did not relish Harrington's joke and filed a complaint against him.

The complainant's daughter, while out riding a short time ago with friends, was drenched. Accordingly Mr. Beers and his daughter insist that Harrington should be punished. The charge was not because of any damage sustained by the car or its occupants, but simply for the assault itself.

When the trial took place last week, 47 witnesses were subpoenaed in the case, many of whom were fashionable residents of the neighborhood, where the squirting took place—most of whom testified. Miss Beers and others swore that her automobile was running very slowly. It was an all-day trial, the jury being charged at 4 p. m. That night, the twelve men announced that the could not agree on a verdict, so tha justice was forced to grant a new trial. Meanwhile Harrington has suspended his squirting operation.

How Wareham is Checking Speeding.

Speed banners as a means of reducing the number of cars that rush through the town's main street at a dangerous pace have been found successful in Wareham, Mass. The automobile club of that place has had the flaring banners up for about a month on the road approaches to the business portion of the town and motorists in general have respected the requests for slow speed. The few exceptions have had their numbers taken and are being written to by the club, asking a more courteous observance of the club's signs. Wareham is one of several towns in Massachusetts where this plan is on trial. It was one of the towns noted for its "traps," the operation of which has been suspended pending the success of the banner experiment.

BUMPERS FOR GRADE CROSSINGS

Long Island Railroad President Evolves Scheme to Halt Reckless Chauffeurs—Its Adoption a Probability.

President Ralph C. Peters, of the Long Island Railroad Company, who of late has been paying as much attention to automobiles as he has to the net work of rails and tracks which cobweb Long Island, has hit upon a happy scheme to eliminate or reduce grade crossing accidents. At least, Mr. Peters considers the scheme a good one, and this opinion is held also by Alfred J. Eno, president of the Long Island League; A. R. Pardington, general manager of the Long Island Motor Parkway, and John L. Webb, chairman of the committee of safety of the Long Island Automobile Club.

These gentlemen met in Mr. Peters' office in Long Island City on Monday afternoon and after mature deliberation evolved a plan for establishing a series of bumps that will outbump the Glencoe, Elgin, Aurora, and other excrescences designed to put the "kibosh" on speeding tendencies of reckless chauffeurs.

In short, it is planned to construct a hummock about a foot high in the road on each side of the grade crossing and 150 feet from them. It is figured that drivers will then be compelled to slow down or run the risk of breaking the springs of their cars. Mr. Eno said that this plan had worked in Babylon where all other methods to stop the reckless speeding of motor cars had failed.

President Peters contended that flagmen at grade crossings are practically useless and that it would be impossible to place a watchman at every crossing, as there are 429 of them on Long Island. He said that his company would be willing to bear half the expense of constructing the bumps and Mr. Eno said that he would take it up with his league and propose that it bear the other half.

One of the attendants at the meeting proposed that the railroad company make depressions in the road instead of bumps, but when it was pointed out to him that the hollows in the road could not be seen by approaching drivers, while the bumps would appear formidable from a distance, he was won over to the original plan.

Automobile Road to Succeed Tow Path.

The old tow path of the long abandoned Pennsylvania canal along the picturesque lower Susquehanna is to be converted into an automobile road. The Wrightsville and Chanceford Turnpike Co. is planning to make the tow path part of a motor road system between Wrightsville and Long Level, Pa., opening up a wealth of beautiful scenery to the tourist.

CONEY ISLAND COPS CAPTURE CARS

Unattended Vehicles "Arrested" and Locked Up—Wobbly Wheels Cause One to Register as a 'Plain Drunk."

It was an eventful night when seven touring cars, which were standing untenanted and untethered to posts along Surf avenue, Coney Island, were confiscated by Capt. Kelly, of the Coney Island police force, from which one would be led to imagine that the captain is fond of fine automobiles. The charge against these seven arrested cars, however, was that they were without care takers and obstructing traffic. The machines were also charged with vagrancy. One had wheels that wobbled and it was entered on the blotter as a "plain drunk," it is said. Pursuant to this, all seven cars were sent from the station house at 2 a. m. to be locked up in a garage on West Seventieth street, and the captain's command was that they should not be removed until he gave orders for their release. All remained there over night except two. One was bailed out by its owner and the other broke jail and escaped, which greatly displeased the captain's subordinates when it caused the captain to become exceedingly riled.

Not until after much long delay and payment of storage charges, could the drivers obtain their cars and at that, the owners had to promise solemnly that they would never again permit their cars to be on the streets alone after dark and obstruct traffic along the busy and brilliant main thoroughfare of the gay summer city by the sea.

The crusade, it is said, follows a complaint in court recently when a taxicab chauffeur and a cabby fought after being arrested for obstructing the highways. The taxicab people complained that if they were kept on the move every one should be treater alike and thereupon the crusade against private cars began. It seems that the captain started out about 1 a. m. with a squad of reserves in plain clothes. He hailed two men who could run automobiles and after enlisting them as volunteers, detailed them with the reserve squad. The reserves were given orders to pick up every car that was without an attendant along Surf avenue. The policemen went forth and the first "capture" was in front of Henderson's. There was a large 90 horsepower gray Thomas touring car which seated eight persons on the street close to the curb. No one was watching it and one of the "volunteers" took his place at the steering wheel and piloted the car to the police station.

The chauffeur was again sent out, and found another car near the corner of Henderson's walk and Surf avenue in charge of a sleuth. It had been captured without a struggle, while the owner was apparently looking upon the wine when it was pink. It was sent to the station, too. By this time word began to get around that the police were picking up the cars, and the chauffeurs sat on their machines and gave the policemen the laugh. At least the majority of them did. Seven altogether were amiss, and their machines were taken to the station.

About 3 G. M., John Comparr, who gave his address as the New York Yacht Club, appeared and reported that his car had been stolen. He was asked where he had left the machine and gave a description of it. Capt. Kelly in person took the complaint and recognized the machine which fell into his care first, a big gray touring car. Mr. Comparr was given a severe lecture about the evils of leaving a machine to block the highway and an order on the manager of the garage for his machine. He paid the storage charges, got his machine and left the Island.

Then Capt. Kelly waited for other complaints, but none came. The owners, it was said, had received a "tip" that the police had their cars and they refused to make a break to get them until they could learn the nature of the charge against them. Some of the machines could not be removed by their owners for a couple of days, as the morning after the raid, the captain went off on a little vacation. Beware the Coney cop, my son!

Losing a Passenger En Route.

If Genevieve's mother had particularly impressed upon you the fact that you must drive very carefully, because it would break her heart if anything should happen to her only daughter, and you had solemnly promised to pay strict attention to driving and use both hands on the steering wheel, and to prove it had put Genevieve in the rumble seat while you took the seat in front —(take a breath here)—and bearing mamma's injunction in mind all the while you had carefully watched the road ahead for seven miles, not turning around once for a chat-a-chat, until you drew up to the ice cream parlor and jumped out intending to help Genevieve alight when—say, wouldn't it make you feel like a limp dish rag if no Genevieve was there?

Well, that is the way F. L. Dayton felt when he slowed up at Mount Carmel, Conn., late Saturday night and found that his young woman companion had been bounced from the rumble seat some place between there and seven miles back. Dayton drove back slowly and searched for miles, but no trace of his erstwhile rumble seat companion could be found, and inquiry at the hospitals did not give him any information. In fear and trepidation he made his way to Miss Genevieve's—or whatever her name was—home, and what was his surprise to find her safe and smiling. Although it has not officially been confirmed it is thought that Dayton will remove the rumble seat from his car, at least when he takes Miss What's-her-name out again.

AUTOMOBILES BANISH MOSQUITOES

Long Island Paradise Where the Buzz and the Bite are Unknown—A Summer Colony of Motorists.

One of London's brilliant scientists declared a few days ago that fumes and smoke coming from the exhausts of motor cars killed germs and bacteria and bacilli and the like. Whereupon other scientists made a guy of him. Nevertheless, smoky exhausts will do something just as important, according to the cottagers of Southampton, Long Island, for they have discovered that gases pouring from the cylinders kill mosquitoes. Long Island has long vied with New Jersey as a mosquito reservation and the newly discovered means of getting rid of these annoying birds is a boon to Southampton's residents. According to reports, everyone who drives a motor car is assisting in the extermination by burning quantities of cylinder oil and shooting the smoke all along the line. It is not pleasant for the natives, but they are putting up with the treament, since the mosquito crop is noticeably diminishing.

Old Agawam Lake, on which is the residence of Elihu Root, occupied this season by Nathaniel Holmes; the residence of Col. Robert M. Thompson, J. P. Robb, and that of Stephen Peabody, is being freed from the pests. Along Job's Lane, at the foot of the lake, run daily the eight cars of Hugh J. Grant, ex-Mayor of New York; the four of August Belmont, Jr., three each of James Parrish and Stephen Peabody, and the two of Dr. Maitland Alexander. Before the season is over, these residents of the cottage colony expect to get in some good work, and the dealers in summer board will be able to truthfully advertise: "Delightful country—no mosquitoes!"

Working for Speed Law Observance.

The Automobile Club of Bridgeport, Conn., has been doing good work lately in endeavoring to have automobiles observe a reasonable rate of speed. Circular letters have been sent to the members by the Public Safety Committee, giving the sections of the law most often violated and asking members to join in supporting the law, for which the club was partly responsible in having it passed, and which is one of the most liberal in the country.

The Public Safety Committee has been following up this action with personal letters to owners of cars where flagrant violations of the law have come to its notice. On a recent Sunday the committee placed flagmen on Connecticut avenue, a wide and much traveled thoroughfare, forming the eastern approach to the city. Automobilists were halted and handed a card which asked that a reasonable speed be preserved on this street and through the city.

The Week's Patents.

889,960. Running Gear for Vehicles. Isaac E. Palmer, Middletown, Conn. Filed Nov. 20, 1907. Serial No. 402,954.

1. In running gear for vehicles in which the members of a pair of wheels to the rear of a pair of steering wheels are arranged out of transverse alignment, means for swinging a rear wheel out of its normal plane to compensate for lateral drag in turning a curve.

889,996. Automobile. George A. Weidely, Indianapolis, Ind., assignor of one-half to Harold Smith, Indianapolis, Ind. Filed June 1, 1907. Serial No. 376,824.

1. In a motor vehicle, the combination, with the driving shaft, of a carrying wheel mounted upon said shaft and having a rotative engagement therewith, of a bearing engaging both the shaft and wheel, and a second bearing for said shaft.

890,571. Gas Engine. Ransom E. Olds and Horace T. Thomas, Lansing, Mich., assignors to Reo Motor Car Company, Lansing, Mich., a Corporation of Michigan. Filed July 10, 1907. Serial No. 382,976.

1. In a six-cycle gas engine, an exhaust apparatus adapted to relieve the pressure toward the end of the working stroke, a second exhaust apparatus adapted to convey the products of combustion remaining after the gases under pressure have been exhausted, and means for holding said second exhaust apparatus open for the intake and discharge of a scavenger charge, for the purpose described.

890,589. Transmission Gear. Elijah W. Potts, Detroit, Mich., assignor, by direct and mesne assignments, of two-sixteenths to Albert W. Wadsworth, one-sixteenth to Samuel P. Bradley, one-sixteenth to Louis Cohn, and one-sixteenth to Theodore L. Wiggins, Detroit, Mich. Filed Jan. 2, 1906. Serial No. 294,124.

1. In a transmission mechanism, the combination with the driving shaft, of a driving gear wheel supported by but rotatable independently of said shaft, gearing for driving said gear wheel indirectly at variable speeds, comprising gear wheels rotatable in unison loosely mounted on the driving shaft, means for locking said gear wheels to the driving shaft, and means for connecting the driving gear wheel directly to the driving shaft to afford a direct drive and for disconnecting all of the gears of the mechanism from the driving shaft.

890,615. Automobile. Albert G. Davis, Schenectady, N. Y., assignor to General Electric Company, a Corporation of New York. Filed Feb. 8, 1904. Serial No. 192,479.

1. In a self-propelled vehicle, in combination with the frame thereof, a prime mover, an electric generator having its moving member mounted on the shaft of the prime mover, an electric motor having its shaft in line with the shaft of the prime mover, and an auxiliary frame supporting said prime mover, said generator and said motor, and suspended from the said vehicle frame.

890,654. Motor Vehicle. Russell Huff, Detroit, Mich., assignor to Packard Motor Car Company, Detroit, Mich., a Corporation of West Virginia. Filed Oct. 21, 1907. Serial No. 398,451.

1. In a motor vehicle, the combination with the frame, of a baggage rack pivotally attached to the rear part thereof, and steps attached to the spring hangers for supporting said rack.

890,666. Brake Mechanism for Self-Propelled Vehicles. Hermann Lemp and Henry S. Baldwin, Lynn, Mass., assignors to General Electric Company, a Corporation of New York. Filed Aug. 7, 1905. Serial No. 272,990.

1. In a motor car, the combination with a floating axle, of a tubular axle thereon having pins at one end, and a driving wheel on said floating axle having a brake flange engaging with said pins.

890,667. Weather Screen for Motor Vehicles. Joseph Lingley, Peckham, England. Filed May 6, 1907. Serial No. 372,225.

1. In a wind screen for vehicles, a fixed lower part carried by standards and an upper movable part centrally mounted upon centers permanently fixed at the upper ends of solid arms the lower ends of which are mounted upon centers permanently fixed upon the lower fixed part and means for fixing the arms at any desired angle with the lower fixed part and means for fixing the upper movable part at any desired angle with the arms substantially as herein shown and described and for the purpose stated.

890,671. Pneumatic Wheel for Vehicles. Bryce J. Macaulay, Eastbourne, and James A. F. Hall, Hampden Park, near Eastbourne, England. Filed Aug. 12, 1907. Serial No. 388,220.

The combination with that class of pneumatic wheel wherein a supplementary trough shaped tire has its flanges outside the sides of the rim of the felly and wherein the air tube is situated between the rim or felly and the bottom of the said trough shaped tire, of an outer thickened tread, slanting pockets or recesses on or in the outside of the flanges of the supplementary tire, arms attached so as to revolve with the wheel and having correspondingly slanted outer ends which enter easily the said pockets or recesses, resilient cushions at the bottom of the pocket or recesses, and emergency blocks by which the wheel and tire can be held rigidly to the wheel, substantially as hereinbefore described.

890,725. Valve Remover. Berndt A. Swenson, Providence, R. I. Filed Feb. 24, 1908. Serial No. 417,260.

1. In a valve remover, the combination with the body, of supporting means upon the upper portion of the body, a forked member slidably mounted in the lower portion of the body, and cam means upon the body operatively connected with the forked member for actuating said member.

890,742. Liquid Gage. George E. Whitney, East Boston, Mass., assignor, by mesne assignments, to Stanley Motor Carriage Company, a Corporation of Massachusetts. Filed July 26, 1902. Serial No. 117,107.

1. In a liquid gauge, a liquid chamber, a transparent wall therefor and a reflecting surface within said chamber presenting a portion inclined at an angle with said wall in a vertical direction.

890,875. Awning and Dust Screen for Vehicles. Henri S. Samuel, Paisley, Scotland. Filed April 18, 1907. Serial No. 368,925.

1. The combination of a vehicle, a rear frame pivotally connected thereto, means for holding the frame in an upright or in an inclined position, additional frames re-

movably held upright in the vehicle, a rotatable roller extending across the rear of the vehicle, means for supporting the roller, a sheet wound on said roller and extensible therefrom, and securing means carried by the sheet whereby it may be secured over the vehicle to form an awning or to the rear frame to form a dust guard.

890,963. Running Board for Automobiles. Howard E. Coffin, Detroit, Mich. Filed July 18, 1907. Serial No. 384,304.

1. The combination with a running board, a side sill of a vehicle frame and a shield; of a hanger for said running board consisting of a struck up sheet metal arm of U-shape section, said arm curving from a vertical to a horizontal plane, flanges on said vertical portion for engaging said side sill and out-turned flanges upon said horizontal portion for engaging said mud shield.

890,970. Carburetting Apparatus for Explosive Engines. Fritz Durr, Karlsruhe, Germany. Filed March 2, 1907. Serial No. 360,174.

In a carburetter for explosive engines, the combination of a reservoir having therein a centrally arranged tube the lower end of which is above the bottom of the reservoir, and said tube being provided with apertures adjacent its upper end, a cap closing the upper end of the tube and forming an annular chamber about the apertured section thereof, an inwardly opening valve closing an air inlet in a wall of the cap, a hydrocarbon nozzle extending into the central tube, and an annular valve surrounding the tube within the cap and adapted to regulate the passage of air through the apertures in the tube, substantially as described.

890,981. Suspension Frame for Automobiles. Reinhold Herman, Crafton, Pa. Filed April 25, 1906. Serial No. 313,525.

1. An automobile comprising a front and rear axle, a bolster upon each of the axles, a pair of superposed frame members, the upper of which is fixedly connected to the front bolster and movably connected to the rear bolster and the lower of which is movably connected to the front bolster and fixedly connected to the rear axle and a motor supported from said lower frame member at the front thereof.

891,017. Coil Box Switch for Ignition Systems. Richard Varley, Englewood, N. J., assignor to Varley Duplex Magnet Company, a Corporation of New Jersey. Filed March 25, 1907. Serial No. 364,496.

1. In a coil box switch, a coil box having a recess in its front face, blocks in said recess, spring blades projecting downward in parallel directions from said blocks, a rotatable block having segments movable to engage certain of said blades, and having a depending lever, and a plug adapted to be inserted between the remaining of said blades to complete a circuit connection there between.

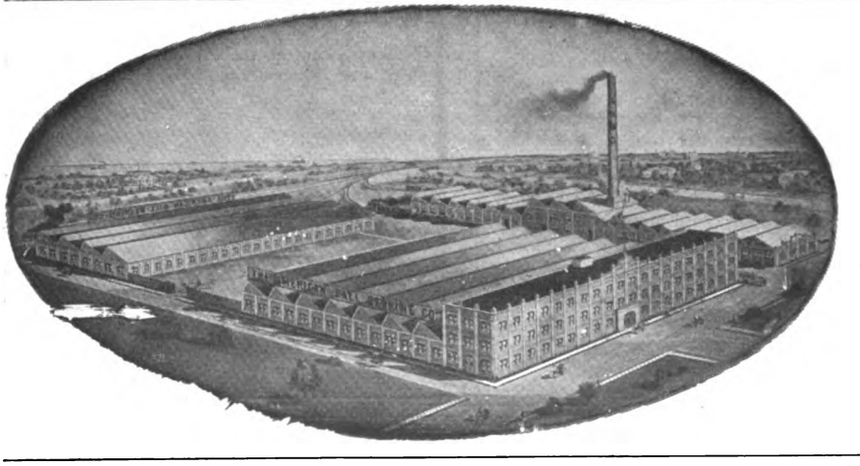
891,030. Armor for Rubber Tires. Vendel L. Bekefi, Cleveland, Ohio. Filed Dec. 9, 1907. Serial No. 405,678.

An armor for rubber tires consisting of a series of overlapping plates substantially U shape in cross ection, and each plate having a transverse depression at one end and outward projections at the ends of said depressions and open slots in the other end lengthwise of the plate engaged by the said projections on the adiacent plate, in combination with a wheel and tire and means to secure the armor on the tire.

891,051. Automobile Construction. Godfrey Engel, Pittsburg, Pa. Filed Sept. 6, 1906. Serial No. 333,456.

1. In a motor vehicle, the combination of a twin engine having multiple cylinders arranged in two rows, each row being connected to a separate crank shaft, the said crank shafts being geared one with the other, and means independent of the gearing between the crank shafts for transmitting power from said crank shafts to the driving agency of the vehicle.

891,169. Spring Tire. Bernhard Hilger, Elgin, Ill., assignor to Frank J. C. Krahn and Morritz Bautsch, Elgin, Ill. Filed June 19, 1907. Serial No. 379,787.



In a wheel, a felly, an outer rim, springs interposed between said felly and rim, a plurality of clips carried by the rim and formed with a portion extending transversely of said rim and with down-turned end-portions, cover plates secured to said down-turned end-portions of the clips, a packing, comprising a strip of soft material, interposed between said cover plates and said rim, and a packing, comprising a strip of soft material, interposed between said springs and said felly and covering the entire periphery of said felly and extending beyond the sides thereof and against said cover plates.

891,172. Wheel Rim. Ernest Hopkinson, East Orange, N. J., and Thomas Midgley, Hartford, Conn.; said Hopkinson assignor to The Hartford Rubber Works Company, Hartford, Conn., a Corporation of Connecticut. Filed July 5, 1906. Serial No. 324,762.

1. In a wheel rim, the combination with a main rim member, of a removable side flange, means for contracting and expanding said side flange, said means comprising a member threaded adjacent to each end, the threads at one end being opposite in direction to those at the other end and adapted to engage threaded sockets in the ends of the side flange, a worm pinion fixed on said member, and a worm in mesh with said worm pinion.

891,219. Carburetter. Albert W. Menns, Malden, Mass. Filed March 6, 1907. Serial No. 360,847.

1. In a carburetter, the combination of a main outlet therefrom for the vaporized mixture, a plurality of float chambers adapted to contain hydrocarbon liquid, a hydrocarbon passage from each of said float chambers, a plurality of mixing compartments each of which communicate through one of said hydrocarbon passages with a float chamber, an air inlet to each of said mixing compartments, an outlet for the vaporized mixture from each of said mixing compartments, and a valve interposed between the said main outlet and the individual outlets or passages from the said mixing compartments, said valve being adapted to cut off one or more of said compartments from the said main outlet.

The output of complete Front and Rear Automobile Axles of this plant exceeds the capacity of all competition combined.

Warner Auto-Meter

GUARANTEED FOR ONE YEAR.

"Thirty Days' Free Trial"

When a manufacturer is willing to send his product to anyone, anywhere, for 30 days—with no deposit, no agreement to buy, no promise to do anything except give that product a fair trial—he must have more than ordinary confidence in his article. In order for him to have that confidence he must have a most extraordinary product.

That's what we do. We'll send an Auto-Meter to any automobile owner in the country—with no deposit, no agreement, no promise to do anything but put it on his car and give it a fair trial. It doesn't matter whether he has another make of speed indicator already on the car or not. Indeed, for the sake of comparison, we hope he has. We will abide by the decision—for he will always keep the indicator that tells the truth. We claim for the Auto-Meter that it is the only one of which "the dial never lies." We believe that the instrument itself is the most eloquent salesman we have—we're willing to let it do our talking. Send to-day—just tell us what make and model of car you have—size of tires, etc.,—and we will send you an Auto-Meter.

BEAR IN MIND

that in eight years there have been five models of Stevens-Duryea Cars. Worked out to perfection before being placed on the market — their mechanical features distinguished for being ahead of the times and because of common sense construction. Contrast the evolution of five unqualifiedly successful Stevens-Duryea Models with the every few months "improvement," radical changes, etc., in the output of some motor factories.

WHEN YOU BUY A STEVENS-DURYEA CAR YOU SECURE A MINIMUM OF UPKEEP EXPENSE AND A MAXIMUM OF PEACE OF MIND.

WRITE FOR DESCRIPTIVE MATTER

DOW TUBES
Are the Most Economical

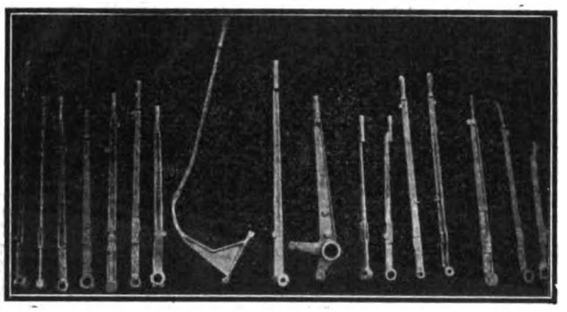
(The Best Tubes Ever Manufactured)

ONE YEAR'S CONSTANT SERVICE IN THE BOSTON FIRE DEPARTMENT

Dow Tire Co., New York, N. Y. Headquarters Fire Department, City of Boston, Bristol Street, Boston, July 20, 1908.

Gentlemen—Having used the Dow Non-Deflation Tubes since August 19, 1907, on the automobile used by Chief Mullen of this city fire department in his response to alarms of fire, I feel that, in return for the excellent results received from these tubes, I ought to inform you of same. Several persons have inquired of me as to their merits, and I have always spoken in the highest terms of them, but never felt that I could write you confirming my statements until such time as they had been in use for about a year.

We have given them all kinds of tests, and will truthfully say that they have withstood all punctures, and with the exception of "blowouts," which are liable to occur with any type of inner tube, they have given excellent satisfaction.



Trusting this letter may be of benefit to you, I remain, Yours very truly, (Signed) JOSEPH A. WEBBER, Lieut., Aide to Chief.

1909
Pope-Hartford Models

Pope-Hartford Model S, Pony Tonneau, $2750

The POPE-HARTFORD 1909 models embody all that is best in automobile construction and will be conspicuous in the foremost ranks of the automobile world.

We invite comparison of the details of POPE-HARTFORD cars for 1909 with those of the world's best motor cars. Because of their perfection, refinement and elegance they will appeal to the superior judgment of critical and discriminating purchasers.

OUR 1909 LINE CONSISTS OF THREE MODELS:

A Standard Touring Car . . . . Price $2750

A Standard Roadster . . . . . Price $2750

A Pony Tonneau Car similar to the above illustration, **Price $2750**

New and important improvements, not incorporated in any other motor car, are included in the POPE-HARTFORD 1909 CARS. Each improvement which we have added has been given a careful and thorough *test,* and our catalog, now in preparation, explains fully all the details and mechanical excellence of the new models. Let us place your name on our mailing list for an advance copy.

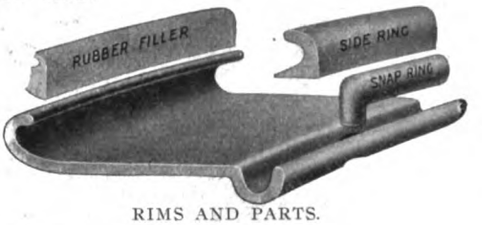
The Standard Universal Quick Detachable Rim



FOR CLINCHER TIRE.

Removed and applied by simply unsnapping or snapping the locking ring. No Turnbuckle to bother with. Accommodates any standard size tire, Clincher, Dunlop or Quick Detachable.

FOR DUNLOP TIRE.

As an evidence of the favorable impression this rim has made upon car manufacturers, it may be stated that it has been adopted by the American League of Automobile Manufacturers as standard equipment for American cars; the change to take place as soon as it can be conveniently arranged.

RIMS AND PARTS.

Morgan & Wright Tires and Standard Rims would furnish a matchless equipment for your car, from the standpoint of both economy and modern rim design.

MORGAN & WRIGHT, Detroit

THE BRAMPTON MOTOR CHAIN

All side plates on both sides of the Brampton Chain are stamped **"BRAMPTON."**

LARGE SALES and SMALL PROFIT with thousands of satisfied customers is our best advertisement. THE BRAMPTON CHAIN is made of self-hardening Steel; the strongest Chain in the World. All parts polished; fits sprockets (that are properly cut) without friction.

Some of the other chains may look like **THE CELEBRATED BRAMPTON CHAIN** because some of the other chain makers began to copy the design and shape of the **BRAMPTON CHAIN** links in 1904. They have improved somewhat on their copied design from time to time until these chains now look more like the **BRAMPTON CHAIN** than ever before. These chains somewhat resemble the **BRAMPTON** in appearance, but the manufacturers of such chains have been unable to copy the material —self-hardening steel.

NO CHANGE IN THE BRAMPTON

There has been no change in the design, construction, material or finish of the **BRAMPTON MOTOR CHAIN** in the past ten years.—**"ENUF SED."**

PRICE

The price being equal, it's presumable you want the best, and full value for your money. In such cases, the **BRAMPTON FILLS THE BILL**, and the prices are the same to manufacturers, jobbers, dealers and consumers as any other chain of equal size. We have in stock chains to fit all American and foreign cars.

YOUR 1909 CAR

You can have the new car that you order fitted with the **CELEBRATED BRAMPTON CHAIN** if you order it that way. No extra cost to either you or the manufacturer. All standard sizes in stock to fit American and Foreign Cars at the same price as the other chains.

SPECIAL CHAINS TO FIT THE INDIAN MOTORCYCLE.

Mongrel or Thoroughbred?

NOW IS THE TIME for you, Mr. Thoughtful Dealer, to decide what you will sell in 1909.

WILL IT BE A MONGREL? a car assembled from parts carried together from all over the country and hammered into shape as well as may be?

OR WILL YOU SELL THE THOROUGHBRED—a homogeneous mechanical masterpiece, every single part of which is the result of the same genius that devised the whole?

"ASTOUNDING," "MARVELOUS," "WONDERFUL," are the terms with which some assembled cars are now tagged, though they are astounding, marvelous and wonderful only to the assemblers, who like Rip Van Winkle, have been dozing in the growing woods of automobiledom and who now, bewildered by the progress that has been going on, seize upon time-tried and long-established practices and herald their adoption by the assemblers as brand-new discoveries.

LET'S REASON IT OUT: On the one hand you have the assembled car, with an engine bought from one manufacturer, a frame from another, and a transmission from a third, and so on down to the last rivet. The maker of the engine, the mill in which the frames are pressed, the transmission man, all derive their separate profits, leaving no other way to the assemblers to obtain their rewards than by skimping the quality of their "product."

AND THEY DO IT—THEY MUST! When you examine some of these astounding cars you will be truly astounded on finding that the four-cylinder engine is cast in one piece and has only two main bearings, whereas the Maxwell has four cylinders and five main bearings. You know well enough that making a motor with only two bearings is equal to leaving the engine to its own devices as far as alignment is concerned.

IT WILL BE A TOUGH JOB FOR THE DEALER to convince the purchaser who is wise that some four-cylinder engines of small dimensions will develop as high as 30 horsepower—because they can't.

MAXWELLS ARE A HOME-GROWN AMERICAN PRODUCT. The use of Maxwell features in Maxwell cars was neither a heaven-given inspiration nor the aping of foreign design, but the outcome of sound engineering sense.

WHEN 10,116 MAXWELL OWNERS testify to the excellence of their cars, all of which have been sold by Maxwell dealers, then the Maxwell proposition is one that you can't afford to pass by.

BEFORE HITCHING YOUR WAGON TO A STAR it will be wise for you to find out all about a dealership for Maxwells, the success of which is past and present, instead of lying in the dark and distant future that has swallowed so many wonderful cars that have been marvelous chiefly in their complete and rapid disappearance from the field of legitimate competition.

Benj. Briscoe
President.

on a midwinter trip from New York to New Orleans, Mr. Ralph Owen driving an **Oldsmobile,** found in plenty, incidents and conditions of the sort that showed the kind of stuff men and things are made of.

When you stop to consider what an automobile is built and intended for, the endurance of this car is marvelous. He says:

"Between Blue Stores and Hudson the road was particularly rough and rutty, and as we were nearing Hudson one of our rear tires was wrenched off in a frozen rut which was nearly eight inches deep. At Buffalo, a thorough examination of the car was made to see if the terrible strain under which it had been the last three days had in any way decreased its efficiency, but aside from a broken spark plug, which had given us some annoyance the last ten miles into Buffalo, nothing was discovered."

This Car was equipped with **TIMKEN ROLLER BEARINGS AND AXLES**

Has it ever occurred to you WHY the manufacturers invariably equip the cars they pick for such trips, with **Timken Product?** There is a reason. May we give it to you?

THE TIMKEN ROLLER BEARING AXLE COMPANY, Canton, Ohio

BOSCH

"No Ignition Trouble Whatever"

says Geo. Schuster, Driver of the winning Thomas Flyer, in the New York to Paris Race.

New York, Aug. 20th, 1908.

BOSCH MAGNETO CO., New York City.

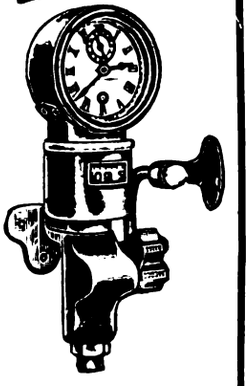
Gentlemen: The performance of the Bosch Magneto was just as remarkable as the performance of our Thomas car. At times when it was necessary to ford streams, and water was thrown over the top of the bonnet of our car, I was sure we'd have magneto difficulties. On the contrary, we had no trouble during the entire trip. Perfect Ignition all the way from New York to Paris. The Bosch Magneto is perfect.

Yours truly GEO. SCHUSTER.

BOSCH MAGNETO COMPANY, 160 W. 56th Street, New York

Chicago Branch, 1253 Michigan Avenue.

Warner Auto-Meter



GUARANTEED FOR ONE YEAR.

"Thirty Days' Free Trial"

When a manufacturer is willing to send his product to anyone, anywhere, for 30 days—with no deposit, no agreement to buy, no promise to do anything except give that product a fair trial—he must have more than ordinary confidence in his article.

In order for him to have that confidence he must have a most extraordinary product.

That's what we do. We'll send an Auto-Meter to any automobile owner in the country—with no deposit, no agreement, no promise to do anything but put it on his car and give it a fair trial. It doesn't matter whether he has another make of speed indicator already on the car or not. Indeed, for the sake of comparison, we hope he has. We will abide by the decision—for he will always keep the indicator that tells the truth. We claim for the Auto-Meter that it is the only one of which "the dial never lies." We believe that the instrument itself is the most eloquent salesman we have—we're willing to let it do our talking. Send to-day—just tell us what make and model of car you have—size of tires, etc.,—and we will send you an Auto-Meter.

Standard Detachable Rim

Resolution passed by the NATIONAL ASSOCIATION AUTOMOBILE MANUFACTURERS at a meeting held in New York, August 5th, 1908.

"Whereas, the Standard Universal Rim, described in the report of "the Special Rim Committee, has been recommended by the committee "as mechanically satisfactory, be it

"RESOLVED that this association hereby adopts the rim so de- "scribed as standard, subject to the consummation by the Special Rim "Committee of satisfactory commercial arrangements with the patentee "and manufacturers."

At the above meeting all the detachable rims now on the market as well as proposed new rims were carefully considered.

THIS IS THE RIM

Rambler

Price $2,250.

THE ADVANTAGES OF THE OFFSET CRANK SHAFT

Here is a simple explanation of the offset crank shaft, the great power developing feature of the Rambler.

Notice a man about to mount a bicycle. He always adjusts the pedal in that position where it will receive to best advantage his full weight on the first downward stroke. The best position for the pedal is just slightly forward of the center of the crank shaft on the bicycle. If he mounted when the pedal was directly over the center of the crank shaft, his weight would fall directly on the bearings and the first downward stroke would be retarded and, therefore, weak.

Now imagine the man's leg as the piston of an automobile engine; the pedal of the bicycle as the crank pin and the crank shaft of the bicycle as the crank shaft of the engine. In the ordinary engine the crank pin and piston (the pedal and the man's leg) are directly over the dead center and until the crank passes the turning point all effort is wasted. Thus, when the explosion occurs, the greatest force falls upon the bearings.

In the Rambler engine at the instant the explosion occurs above the piston the crank pin has moved past the dead center; the crank shaft is in a position to receive the full pressure and turns without friction. Consequently there is no side thrust of the piston and wear on the cylinder walls is thus saved.

Try this Rambler on the hills and notice how steadily and powerfully it pulls when running under load.

Tell our nearest representative to call at your home and take you to your place of business in a Rambler.

In the Chancery Court at Newark, N. J., on Tuesday last, 8th inst., Vice-Chancellor Howell continued for two weeks an order directing parties in interest to show cause why the receivers for the Pope Mfg. Co. should not be compelled to pay a third dividend of 25 per cent. to the holders of approved claims.

It was represented to the court by Percy S. Bryant, counsel for the creditors' committee, that the receivers have on deposit in various banks cash in excess of $800,000, and that $379,000 would suffice for the payment of the dividends.

The application was opposed by Sherrerd Depue, representing the receivers. Mr. Depue read a communication from George A. Yule, who was appointed one of three receivers at the instance of the creditors' committee, in which Mr. Yule stated that he was not in favor of granting the application at present. Mr. Depue stated further that the time limit for the adoption of a proposed reorganization plan expired on Tuesday and he urged that the outcome of that proposition should be awaited. The plan, he said, provided for the payment in full of all claims immediately upon its adoption. It is understood that a sufficient number of shares has been deposited with the stockholders' committee to assure the success of the reorganization plan as outlined.

The vice-chancellor disposed of the application by saying that he thought he ought to give the reorganization scheme a chance and to that end he continued the application to September 22.

Half Million Dollar Fire in Boston.

Fire from an unknown cause destroyed all but the second floor of the big Taylor-Palmer garage, at 169-171 Huntington avenue, Boston, on Sunday last, 6th inst. Seven employes were in the building at the time the fire was discovered eating its way from the basement to the first boor, and they had time to remove only two cars from the building before the kames gained headway. Between 50 and 60 cars were destroyed, a majority of them belonging to Boston people who are away for the summer. The loss is estimated at about $500,000.

Court Authorizes Pope-Waverly Sale.

As soon as the Indiana court has had an opportunity to give its approval, of which approval there is practically no doubt, the sale of the Pope-Waverly plant in Indianapolis will be consummated by the receivers of the Pope Motor Car Co. to the interests represented by Herbert H. Rice and Wilbur C. Johnson. The chancery court of New Jersey, under the laws of which state the Pope company is incorporated, gave its authority for the sale when the receivers' petition was considered on Tuesday last, 8th inst., and the matter now passes to the Indiana courts within whose actual jurisdiction the factory is located. Messrs. Rice and Johnson, who are connected with the management of the Pope-Waverly business, offered $200,000 for the entire assets, less the cash in bank, and it is this bid that will be accepted. The cash in bank on June 30th last, which will be excepted by the terms of the sale, amounted to $106,420.71.

Muncie Sees Big Factory Coming.

According to press despatches from Muncie, Ind., as soon as title to the site can be obtained, "the construction of a large automobile factory to employ several hundred persons will be started immediately." The factory, it is stated, will be financed by Thomas F. Hart and Madison Maring, Muncie capitalists, and outside interests, "who have practically obtained all the patents for the manufacture of a well known car and who will turn out a machine almost identical with one that has been a success on the market for several years"—name not mentioned.

TO SUE OLDS AND BUICK

A. L. A. M. Makes Sensational Moves—Takes Action to Collect Olds's and Buick's Arrears and to Cancel the Olds License—No Space in Show for Either Concern.

Although surface appearances indicated that little if anything outside of the usual routine was transacted at the meeting of the board of managers of the Association of Licensed Automobile Manufacturers at their New York offices on Thursday last, 3d inst., it has leaked out that sensational action was taken affecting two of the prominent members of the organization, viz.: the Olds Motor Works, of Lansing, and the Buick Motor Co., of Jackson, Mich.

It seems that both of these companies were among the number that withheld payment of the Selden royalty pending the adjustment of the demand for a reduction of the royalty fee, which reduction was authorized by the courts in June last, and which was made apply to the two quarterly settlements then overdue. According to the best information obtainable, Olds and Buick have not only not made those payments, but have neglected or refused to make settlements for the succeeding quarter. All efforts to amicably obtain the amounts due for the period of nine months having failed the A. L. A. M. last week agreed that the time for temporizing having past, stern action was necessary.

To that end, a resolution was unanimously adopted which requests the Electric Vehicle Co., as the owner of the Selden patent, to institute legal proceedings for the collection of both the Olds and the Buick accounts and also in the case of the Olds Motor Works to have it show cause why its license under the Selden patent should not be revoked and cancelled. For some unknown reason, no effort will be made to nullify the Buick license, at least, not at

Digitized by Google

this time. Additional significance is added to the situation by the fact that in the allotment of space at the forthcoming Madison Square Garden show, which was made last week, Olds and Buick were passed over and did not share in the apportionment.

This action on the part of the A. L. A. M. is certain to create a furore. None outside of its innermost circles even suspected that anything of the sort was in contemplation, at any rate, not so far as the Olds interests are concerned. The Olds Motor Works was one of the original members of the association and has always stood high in its councils and played an active and conspicuous part in its affairs, F. L. Smith, general manager of the Olds company, having been at one time president of the A. L. A. M. According to one story, the Olds people were opposed to the grant of a license which recently was issued and assumed their present attitude as evidence of their displeasure. The Buick Motor Co., on the other hand, never has been active in the association's affairs and rarely has been represented at its meetings despite the fact that it has profited enormously from its membership. It has been one of the few Selden licensees making a low priced car and because of the exclusive agency policy that obtains in the licensed organization, the Buick company, almost without effort, has been able to secure agents and place its goods in a great number of desirable places.

W. C. Durant, general manager of the Buick company, was among those present at last Thursday's meeting at which this radical action was determined, but the Olds interests were not represented. At the same meeting of the A. L. A. M., a step also was taken to open wider the door of the association and to disprove reports that the bars are up against additions to the membership. The step took the form of a resolution, passed without a dissenting voice, which made it the sense of the meeting that applications of other manufacturers who measure up to the A. L. A. M. standard be considered.

Those in attendance at the meeting were as follows: Autocar Co., Marcus L. Brock; Buick Motor Co., W. C. Durant; Cadillac Motor Car Co., W. C. Leland; Corbin Motor Vehicle Corp., M. S. Hart; Chalmers-Detroit Motor Co., R. D. Chapin; Electric Vehicle Co., H. W. Nickolls; Elmore Mfg. Co., J. H. Becker; H. H. Franklin Mfg. Co., G. H. Stillwell; Hewitt Motor Co., E. R. Hewitt, R. C. Gildersleeve; Locomobile Co. of America, S. T. Davis, Jr., A. W. Robinson; Lozier Motor Co., H. A. Lozier, Jr.; Matheson Motor Car Co., C. W. Matheson; Northern Motor Car Co., V. M. Gunderson; Packard Motor Car Co., H. B. Joy, M. J. Budlong; Peerless Motor Car Co., L. H. Kittredge; George N. Pierce Co., Chas. Clifton; Pope Mfg. Co., C. E. Walker; Pope Motor Car Co., George Pope; Royal Motor Car Co., E. D. Shurmer; Selden Motor Vehicle Co., R. H. Salmons; F. B. Stearns Co., F. B. Stearns; Stevens-Duryea Co., C. C. Hildebrand; Studebaker Automobile Co., W. E. Metzger; E. R. Thomas Motor Co., E. R. Thomas; Waltham Mfg. Co., E. S. Church, O. G. Bechtel; Winton Motor Carriage Co., Thomas Henderson; and E. P. Chalfant, assistant general manager A. L. A. M.

The Week's Incorporations.

Louisville, Ky.—Miles Auto Co., The, under Kentucky laws, with $10,000 capital. Corporators—Leon L. Miles, William H. Curtis, Sr., and Ada B. Harris.

Dover, Del.—International Auto Cab Co., under Delaware laws, with $500,000 capital. Corporators—F. P. Jones, F. W. Mills, E. J. Forham, New York City, N. Y.

Chattanooga, Tenn.—Burk Auto Co., The, under Tennessee iaws, with $10,000 capital. Corporators—Anton Pyron, Thomas W. Fritts, Sidney B. Elmore, Albert Rodgers and W. W. Burk.

Denver, Col.—Denver Auto Service Co., under Colorado laws, with $100,000 capital. Corporators—J. Wesley Smith, Rodney J. Bardwell, W. V. Elliott, R. C. Hecox and C. H. Smith.

Indianapolis, Ind.—Southern Indiana Automobile Co., under Indiana laws, with $30,000 capital. Corporators—Harley Jackson, William P. Masters, Fred Everback, Isaac Elbert and Clark B. Davis.

New York City, N. Y.—Precision Tool & Instrument Co., under New York laws, with $100,000 capital; to manufacture engines, machinery, motors, tools, etc. Corporators—J. A. Straussman, E. M. Munn, New York City, N. Y.; J. F. Brown, Brooklyn, N. Y.

In the Retail World.

The Milford Auto Machine Co., Milford, Mass., is about to remodel and enlarge its present premises; the addition will be 40x30 feet.

Fire last week completely destroyed Edward C. Truncer's garage at 77 Virginia place, Buffalo, N. Y. Ten automobiles were wrecked, the total loss being more than $25,000.

The Elmore Motor Co., of Los Angeles, has begun the erection of its new garage at 742 South Olive street. Its dimensions will be 80x167, and it will contain all modern improvements.

J. F. Ollinger has purchased an interest in the Center Motor Car Co., Salina, Kan. His entry has carried with it a change in the name of the concern to the Ollinger-Center Motor Car Company.

T. G. Patterson and Dr. William Marseilles have rented a disused candy factory on North Washington street, Clinton, Mo., and will remodel and use it as a garage. The first named will have active charge of the business.

The Smith-Clemens-Hopping Garage, at Dayton, Ohio, has removed to the Majestic rink building, that city. There has been no change in the personnel of the company as has been reported, and it will continue to handle the same line of cars next season, namely, Thomas, Chalmers-Detroit, Cartercar and Columbus.

George S. Hill, the directing head of the Hill Garage, at Haverhill, Mass., has withdrawn, and Elmer C. Bassett, of Boston, assumes the position of manager; Bassett has secured a controlling interest in the plant and business.

The automobile, bicycle and sporting goods department of House & Herrmann, Wheeling, W. Va., has been purchased outright by Wesley T. House. The new owner has managed this department of the business since it was started.

The Denver Automobile Service Co. has been incorporated in the Colorado city of that name to do a general automobile business. J. Wesley Smith, Rodney J. Bardwell, Willis V. Elliott, Roy C. Hecox and Charles H. Smith are the corporators.

Willis, Haywood & Holcomb is the name of a new company that has opened in Indianapolis. The garage at 330 North Illinois street, formerly occupied by the Fisher Automobile Co., has been remodeled, for the exploitation of Packard cars.

H. J. Donohue, a retired merchant of Sumner county, Kan., now located at 351 North Topeka avenue, Wichita, has decided to enter the business arena again. This time it will be automobiles instead of dry goods, and the Lambert is the car he has decided to represent.

A short circuit of electric light wires causing an explosion of gasolene was responsible for the burning of the garage of Ball & Staolers at Devils Lake, N. D., on August 27th. Twenty cars were saved but the loss to machinery and building amounted to $15,000, on which there was no insurance. The garage was one of the largest in North Dakota.

The Ellis Motor Car Co., Newark, N. J., has moved into its new building, 124-126 Washington street, where it will continue to handle the Pierce-Arrow cars. The building, erected expressly for the company, is about 50 feet wide, 100 deep, two stories high in front, and is of fireproof construction. The ground floor is used as a salesroom and garage. The repair shop and storeroom occupy the second story.

The Apthorpe Motor Car Co, is the style of a new concern which has taken possession of the new fireproof garage at 214-216 West Eightieth street, New York. In addition to doing a general garage and repair business, the agency for a line of high-grade cars will be taken on. Fred S. Dickinson is the active man in the company which he states will make a specialty of paying real attention to its patrons' cars instead of paying commissions to chauffeurs.

JULY ANOTHER MONTH OF DECLINE

Export Figures Show a Continued Decrease with Gains in Only Four Countries—The Showing for Seven Months.

No upward tendency in the export of American motor cars and parts came about during the month of July, the total for the month being $643,901 as against $796,325 for the corresponding month in 1907. The returns, of course, brought no improvement for the record of the year so far, and the total for the seven months ending with July was $3,613,941 as against $4,245,490 for the same period last year.

Declines for the month are shown in all but four of the fourteen divisions in which exportations are grouped, the increases being one from $21,992 to $54,555 in "Other Europe", a gain from $1,585 to $5,497 in British East Indies, an advance from $5,731 to $11,247 in Other Asia and Oceania, and an increase from 183,508 to $191,927 in British North America. The more notable declines are those of France, Germany, Italy and Mexico. The exports to France dropped from $121,627 to $53,602 for the month, Germany from $47,720 to $22,744. Mexico from $49,113 to $11,726, and Italy from $14,161 to zero. The loss in the case of the United Kingdom, the biggest customer on the list, was more limited in proportion being a decrease from $301,126 to $273,396.

The seven months' record shows a total gain in the case of the United Kingdom, the figures for 1907 and 1908, respectively, being $1,335,170 and $1,365,561. France, too, despite the July showing, records a gain for the seven months, from $482,868 to $510,758. The trade with Other Asia and Oceania, which showed a July gain, has almost doubled during the first part of this year, with an increase from $45,828 to $88,273. The division known as "Other Countries" also records a seven months' gain, from $7,005 to $18,235.

The record in detail is as follows:

	July		Seven Months Ending July		
	1907	1908	1906	1907	1908
Automobiles, and parts of	.....	.....	$2,356,110	.....	.....
Automobiles	$727,391	$588,560	$485,672	$3,825,969	$3,223,166
Parts of	68,934	55,341	27,507	419,521	390,775
Exported to—					
United Kingdom	301,126	273,396	829,913	1,335,170	1,365,561
France	121,627	53,602	256,036	482,868	510,758
Germany	47,720	22,744	100,106	144,843	123,531
Italy	14,161	.....	233,872	241,100	219,136
Other Europe	21,992	54,555	163,975	233,234	164,554
British North America	183,508	191,927	506,133	900,386	692,836
Mexico	49,113	11,726	381,367	452,611	187,034
West Indies and Bermuda	10,028	5,885	189,282	153,350	105,523
South America	31,821	7,003	72,316	128,490	79,850
British East Indies	1,585	5,497	21,317	19,724	17,560
British Australasia	3,560	4,362	76,833	94,855	37,734
Other Asia and Oceania	5,731	11,247	24,436	45,828	88,273
Africa	3,735	1,930	9,622	6,026	3,356
Other countries	618	27	4,081	7,005	18,235
Total automobiles and parts of	$796,325	$643,901	$2,869,289	$4,245,490	$3,613,941

Engineers to Meet in Cleveland.

Cleveland has been selected as the place for the third quarterly meeting of the Society of Automobile Engineers, on September 18 and 19 next. The Hollenden House will be the headquarters and the program as already outlined will devote considerable time to visiting automobile plants located in Cleveland. The entire morning of the first day will be given over to this, followed by a lunch to be arranged for by the local committee. The afternoon and evening will be devoted to the business meeting and the reading of papers. On the second day a train will be taken to Akron for a visit to the Diamond and other tire plants in that city. The visiting members will be guests of the Diamond Rubber company at a lunch to be given at the Akron County Club. Afterward the Society will go to Canton, where they will visit the plant of the Timken Roller Bearing Axle Co., and the members will be guests of the latter company until their departure from Canton in the evening.

Pittsburg Dealers' Association Election.

At its annual meeting on Thursday last, 3d inst., the Automobile Dealers' Association of Pittsburg elected the following officers: W. H. Murray, president; A. L. Banker, vice-president; Charles F. McLaughlin, secretary; U. P. Moore, treasurer. The Diamond Automobile Co., the Maxwell-Briscoe Pittsburg Co., and the White Co. were added to the membership.

Franklin Adds New Factory Building.

The H. H. Franklin Mfg. Co., are just taking possession of the latest addition to their factory. It is a concrete fire-proof building 97 by 62 feet, five stories high. This building will permit of a greater production of both commercial vehicles and motor cabs.

Building a Factory in Galesburg.

Work on the construction of an automobile factory in Galesburg, Ill., for E. H. Ovelhort is reported as having commenced last week. The building will be of concrete, 60 by 100 feet.

AGAIN THE SPRING WHEEL APPEARS

Latest of the Family Arises in Far Off Arizona—$3,000,000 Company to Make It Go Around.

If the plans of H. O. Jackson and G. F. Randall do not go awry, the poor old pneumatic tire which has endured so many years will have a lot of air let out of it. Its old familiar enemy, the spring wheel, is giving it another poke, so to speak. Messrs Jackson and Randall are the exploiters of the very latest of the large family of spring wheels, the first of which appeared when the bicycle was young and tender.

The two gentlemen, with Jackson as president, and Randall as secretary-treasurer, have formed a $3,000,000 company and incorporated it away out in Arizona, where the Grand Canyon is located. Quite a bunch of the three millions in shares is for sale and if any one desires any of it he has but to speak up and produce the coin.

The first news of the big flotation came not from far off Arizona, but from the little town of Batavia, in Illinois. Mr. Randall appeared there last week in a solid tired automobile equipped with his spiral spring wheels, and "showed" the natives how he could drive over tacks and broken glass and bounce up and down. It tickled their fancy so well that it is stated that the Batavians purchased some $5,000 worth of the Arizona paper.

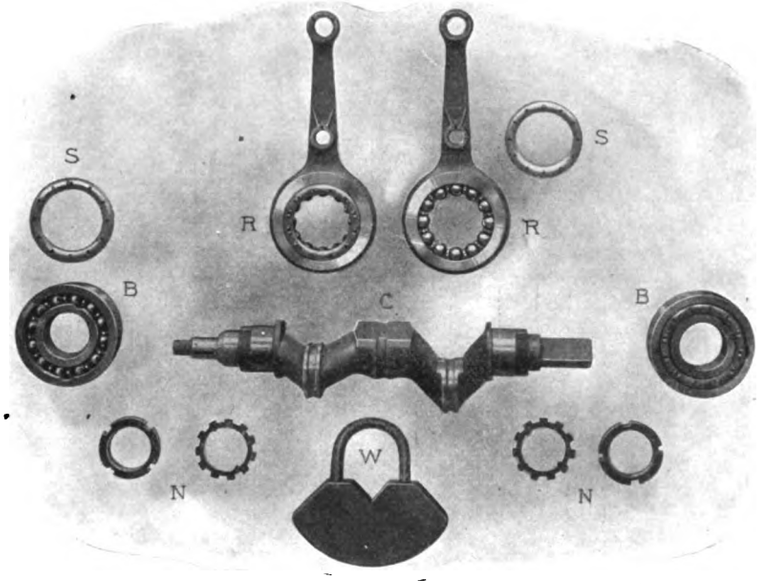
Lausen Changes Name; Will Produce Cars.

The C. P. & J. Lausen Co., which has been making gasolene engines at 841-847 Thirtieth street, Milwaukee, has increased its capital stock from $75,000 to $150,000, and will henceforth be known as the Christenson Engineering Co. The present plant will be enlarged to provide facilities for the manufacture of complete cars.

Continental Adds New Flat Tread Tire.

The Continental Caoutchouc Co. this week announced the addition of a new tire to its line, the A. C. Flat Tread as it is styled. It has a corrugated surface and will be sold at round tread prices and with a 3,500 miles guarantee. It is particularly designed for use on heavy, low powered cars.

Marvel May Locate in Elkhart.



The Marvel Automobile Co., of Detroit, is reported negotiating for a disused factory building in Elkhart, Ind. J. C. Forster, president of the concern, was in Elkhart last week looking over the ground.

Stewart & Clark to Open in New York.

The Stewart & Clark Mfg. Co., of Chicago, manufacturers of the Stewart speedometer, are making ready to establish a branch in New York. It will open soon.

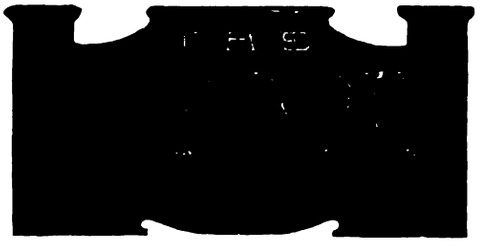
The Simplicity of
THE WHITE STEAM CAR

In the principles of construction—as in the method of operation—the White Steam Car is simpler than any other type of automobile. Consider, for example, the design of the White crank-shaft and compare it with the corresponding member in other cars. In the above illustration is shown the crank-shaft of the 1909 White engine and all the parts attached thereto. The crank-shaft, C, is a short one-piece forging of tool steel with but two main bearings, B,B. These bearings may be removed by taking off the lock nuts and lock washers, N,N. The two connecting rods R,R, are one-piece forgings fitted with ball bearings, as shown. With the addition of the counter weight, W, the crank-shaft is complete.

In all accepted types of gasoline engines there are from three to seven main bearings. As is well known, when any shaft has more than two bearings, there is the ever-present danger that they will work out of alignment. Moreover, the crankshaft of the gasoline engine has either four or six connecting rod bearings, which are invariably only plain bearings instead of ball bearings. It will thus be seen that there are only from one-half to one-third of the number of parts used in connection with the White crank-shaft as are used in connection with the crank-shaft of a gasoline engine.

Next week we shall compare the two valves of the White engine with the eight or twelve valves of the gasoline engine.



Write for circular containg details of the new White cars.

No Cause for Compromise or Controversy.

During the past week, the air and the New York newspapers have been charged with reports that a compromise was in sight in the A. A. A.-A. C. A. controversy. These reports, which significantly enough came chiefly from those who manufactured the controversy, stated that the manufacturers had taken a hand in the matter and likely would force a settlement; and undoubtedly several manufacturers did seek to pour oil on the troubled water, but without effect. The lack of results is not surprising; for it is difficult to discern what there is to compromise.

Shorn of the elements of personal greed and personal grudges, which are at the bottom of the whole affair, it is not easy to see wherein the American Automobile Association has anything to arbitrate. It has not made war on any person or any organization. It simply stands for America and American institutions, of which the Vanderbilt cup race is one. On the other hand, the so-called Automobile Club of America, which stands for Europe and European institutions, has made war on the Vanderbilt race. It has promoted a counter event for no other purpose than to injure America's classic race. The American manufacturers, almost as a unit, had declared that they wanted no additions to the list of these big, expensive sporting projects, but their wishes had no weight with the Automobile Club. Its position has been assumed almost wholly to maintain its own repute abroad and to becloud the fact that its attitude and its antagonism toward the A. A. A. grew out of the petulancy of several of its wealthy and more or less important members who, unable longer to dictate to and domineer all the other clubs in New York State, were unwilling to submit to the will of the majority—a truth which the club rightfully is anxious to put as far as possible behind it.

The issues, if such they may be called, are, therefore, very clear and very simple. Individually, the manufacturers, not a few of whom do not even know "what it all is about," hesitate to "take sides," that is, actively, although collectively their national association has placed them on record as supporting the American Automobile Association, than which no other stand is conceivable. But as a matter of calm fact, the American automobile manufacturers owe little, if anything, to the misnamed Automobile Club of America. Its present attitude is in keeping with its past history. It was pro-foreign from its inception. It is pro-foreign to-day. It is American chiefly in name and in membership. It is less than a year ago that one of its former presidents, addressing the American manufacturers, whose guest he was at the time, patronizingly told them that when their cars were as good as those produced abroad, possibly more of them would be used by the members of his club. It was a remark that is a fair index of the policy that rules the club and has ruled it from its beginning.

If, say, such an organization as the Automobile Importers Association of New York, or of America, engineered such a spite race as the A. C. A. is engineering and on the same alleged grounds, to maintain its reputation abroad, also some foreign rules, no American manufacturer would hesitate a moment in giving proof of where he stands. There is not more occasion for hesitancy on the present occasion. If the Vanderbilt cup race is not a signal success, the foreign nations will hug themselves for joy. Its failure or partial success will be their victory. American manufacturers will do well to take this fact close to their hearts.

The Automobile Club of America is just as much of a local body as the Automobile Club of Cohoes. Its dominion extends no further, at least, in this country. By grace of its good friends in Europe, it is able to say that its disqualifications will be respected abroad. But how many Americans have raced abroad or expect to race abroad?

The only real issue is whether, in the interests of Europe, the Automobile Club of America shall be permitted to injure a genuinely American institution and whether American manufacturers will stand aside and see the injury done. As for controversy or cause for compromise, there is none. The A. C. A. is a local club of less than 2,000 members. The A. A. A. is a national organization with 20,000 members. A local club and a national association of whatever nature can have no quarrel over the right of national government.

Importance of the Country Markets.

Like the question of what becomes of all the needles and pins, it is sometimes difficult for any one having a realization of the enormous motor car production in the United States at the present time to conjecture where all the cars go to. The increase of cars in the larger cities, while noticeable, is not sufficient to account for more than a very small part of the total production. The exports of American automobiles, although reaching very respectable figures, likewise answer for a comparatively modest proportion of the output. If, then, the larger cities and the export markets absorb only a minority of the machines, it follows that the small towns and the country must take the balance. And such is actually the case, the small town and country trade at present forming the largest and steadiest market that the makers have.

Some makers there are who concentrate their selling efforts chiefly on the large cities, and the nature of their product is such as to necessitate this policy more or less, since their cars are of a style and price that makes their purchase in small towns quite unlikely. Other manufacturers have paid special attention to the rich field offered by the small towns and the country districts and have left the large

Digitized by Google

cities pretty well alone. As a result their metropolitan fame is nil, but their sales are in many instances many times larger than surface indications would suggest.

Many causes contribute to make the small town a good market for cars. The fairly prosperous resident of a small town has more reasons for the purchase of a car than the city dweller of equal income, and the housing and maintenance of a machine is cheaper for him than it is for his urban brother. The latter is generally well provided with transit facilities between his home and his place of business, and to indulge in the luxury of an automobile means the paying of high city rentals for garage space and altitudinous prices for service and supplies. The activities of a small town resident, on the other hand, are generally so distributed over a fairly wide topographical area as to make the purchase of a car a wise and judicious business investment for purely transportation purposes, quite aside from the pleasure features. No high rentals attach to such ground as he may use for a private garage, while if he entrusts his machine to a local garage concern, the latter is able to make a much better rate than a city establishment. Such excursions as the city automobile owner makes to the outlying districts are generally for pleasure purposes, with no utilitarian justification, but the owner in a small community has frequent occasion to drive to the city on business as well as pleasure. The main element of difference between the two classes, therefore, is that to the city man the automobile is an adventitious luxury to be employed during his leisure hours and to be paid for at a stiff figure for garaging and supplies, while to the resident of the small community a car is a practical aid in his daily affairs, providing him with better transportation than horses afford and giving him ready access to the city when necessary, all at a cost that makes motoring attractive.

The heavy buying of the Middle West, which has during the past year been one of the strongest factors in the trade, is not accounted for by the big cities. The careful cultivation of the small towns by sales organizations designed with that end in view, was what accomplished such remarkable results. In New England, while the sales are credited chiefly to the city agencies, the bulk of the orders have come from the small towns, all within such easy access of the cities, however, as to permit the city agencies to handle the business. The Southwest presents examples of towns so insignificant in size and population as to be mere flyspecks on county maps, which nevertheless have motor car salesrooms and garages enough to make impressive "automobile rows." These establishments find their support in the demand for cars for cross country traveling.

From the low priced buggy type vehicles up to the latest six cylinder machines, the small towns are, as a whole, outstripping the big cities in the volume of their purchases, only drawing the line at some of the highly refined, ornate and expensive limousine body creations which cannot be sold except in the cities, owing to the limited call for electric lights, satin wall tufting, and folding bridge sets and escritoires. The wise manufacturer and the wise sales manager will not overlook the true nature of the sales situation simply through a desire to shine in the big cities.

Salesmen for motor goods, especially the wholesale men visiting the trade, must needs be well equipped with a mass of information and prices that would make the ordinary citizen dizzy. Many of them carry elaborate price books for ready reference, but others, through long practice are able to quote entirely from the head. There is a great demand among the wholesale supply houses for men who are capable of selling this class of goods, since the business requires quite a range of technical information and real selling ability, as well.

As an instance of how carefully salesmen in this line look after their customers, one of the most successful travelers has recently developed a scheme which has swelled his order list quite a little. In a specially ruled memorandum book he keeps a record of the purchases of each of his customers for the year, and before going to see a customer, a few minutes study of the book discloses just what he has bought in the past. After the latter has given orders for everything he thinks he needs, the salesman calls his attention to the fact that in the past he has at about this time put in a stock of this or that, and gives him a list to investigate as to how his stock stands.

It is nearly always the case that the salesman thus is able to point out deficiencies in the dealer's stock that the latter would quite have overlooked had not the salesman kept track of the course of his purchases through the year.

COMING EVENTS

September 7-12, Hartford, Conn.—Connecticut State Fair Association's outdoor show and grand circuit races at Charter Oak Park.

September 11-12, Brighton Beach, L. I.—Motor Racing Association's 24 hours race, Brighton track.

September 11, Springfield, Mass.—Springfield Automobile Club's hill climb on Wilbraham hill.

September 12, Louisville, Ky.—Louisville Automobile Club's race meet at Churchill Downs.

September 14, Chicago, Ill.—Chicago Motor Club's annual economy run.

September 16-17, Long Island—New York Automobile Trade Association's mechanical efficiency test, New York to Montauk Point and return.

September 23-24, New York City.—Dust trials, smokeless exhaust and brake tests, under auspices of New York Automobile Trade Association, Central Park.

September 20, San Francisco, Cal.—Olympic Athletic Club's race meet at Tanforan Park.

September 20-30—Kansas City Automobile Club's endurance run, Kansas City, Mo., to Oklahoma City, Okla., and return.

September 23-24, Boston, Mass.—Bay State Automobile Association's 24 hours endurance run, Boston to Bretton Woods, N. H.

October 6-9, Chicago, Ill.—Chicago Motor Club's 1,000 miles reliability run.

October 7, Philadelphia, Pa.—Quaker City Motor Club's 200 miles road race, Fairmount Park.

October 10, Long Island—Elimination trials for Vanderbilt cup contest.

October 17, Hartford, Conn.—Automobile Club of Hartford's hill climb, Avon Mountain.

October 24, Long Island.—Vanderbilt cup contest.

November 26, Savannah, Ga.—Automobile Club of America's (New York), 400 miles outlaw race for foreign cars.

December 31-January 7, New York City—American Motor Car Manufacturers' Association's annual show in Grand Central Palace.

January 16-23, New York City—Association of Licensed Automobile Manufacturers' annual show in Madison Square Garden.

January 23-30, Philadelphia, Pa.—Philadelphia Automobile Trade Association's annual show.

February 6-13, Chicago, Ill.—National Association of Automobile Manufacturers' show, Coliseum.

STRANG RUNS AWAY AT LOWDLL

Struggle in 254 Miles Road Race is All for Second Place, Strang Leading by 92 Minutes—One Contestant Disqualified—Big Attendance.

In one of the greatest runaway road races ever held, Lewis Putnam Strang, on Monday last, 7th inst., won the Lowell Automobile Club's 254 miles road race over the Merrimac Valley course at Lowell, Mass. Strang covered the distance in 4 hours 42 minutes 35 seconds, an average speed of 53. miles an hour, and finished 1 hour 32 minutes 23 seconds ahead of his nearest competitor—H. F. Grant, in a six-cylinder American Locomotive car.

Strang drove the same Italian made Isotta-Fraschini car which he piloted to victory in the Savannah and the Briarcliff races and the remarkable feature has been Strang's luck with tires. In none of these events has he stopped once on account of tire trouble; and this fact enabled him to draw out a big lead in the race last Monday, while the other competitors were having their troubles with punctures. Strang also had the glory of making the fastest lap of 10.6 miles in the race, covering the sixth lap in 10:53.

William Bourque, in a Knox car, was third in 6:33:29, and George Robertson, Fiat, was fourth in 6:38:31. There were seven starters, but these four were the only ones to finish. Robert Burman in a Buick was making a good fight for second place, when he was disqualified after completing the 21st lap, because he had employed outside help in putting a new radiator and one or two other things on his car.

Of the remaining two starters, Frank Lescault, in a Simplex, was slipping into second place when he had cylinder trouble and withdrew in the 20th round. Charles Basle, in the second Knox car, had trouble early in the game. The bearings of the connecting rod burned out and could not be replaced. The French driver of the American car was tagged out in the 8th lap.

While the race was not the greatest contest that has been held in America, it was, however, an interesting struggle, but most

LEWIS P. STRANG

of this interest was confined to the fight for second place. Very early in the race Strang secured the lead and after that he was never headed, streaking around in the lead every time. The fight for second place, on the other hand, was exciting, as it was not until the last lap that it was assured for Grant.

Possibly it was this fact that kept the big crowd from surging on the course after the first car finished. In the Vanderbilt, the Briarcliff and other races it has been impossible to hold the crowd in check after

LEO ANDERSON, STRANG'S MECHANICIAN

the first two or three cars have finished, and at the Lowell race, where the winner finished from one and a half to two hours ahead of the field, it is bordering on the marvelous that the combined policing and interest of the spectators in the struggle for second place was sufficient to allow the race to finish as races should. In this respect the contest at Lowell was notable.

Another feature well worth mentioning is the fact that the start of last Monday's race did not have any of the flavor of starts of Vanderbilts proper and elimination, Savannah, Briarcliff and other events. In all these the starts have been made at the unearthly hour of sometime between the beginning of daybreak and thrifty farmers' breakfast time—a time when well regulated people are taking their beauty naps. At Lowell the spectators had a chance to get this woodburysnooze plus breakfast and then be on time to watch the cars and drivers make their getaway.

The stage setting of the Lowell affair was like those of other important road events. The thrifty New England farmers were even thriftier than the Long Island and Westchester county tillers of the soil in erecting grandstands, transforming hay fields into parking places, and selling hot coffee and sandwiches in return for the large amount of loose change that always sprinkles plentifully around the scene of a big event of any kind. The Lowell race had not only its "hairpin curve," which was not so very terrible after all, but it also had a "dip of death." This was nothing more than a slight uphill and down again piece of road which would scarcely be honored with the name "hill" in Westchester county, New York. And, as frequently happens on "dips of death" and "hairpin curves," killings persistently refused to happen. In fact, exclusive of tire trouble and a few minor engine mishaps there was not a thriller of any kind, except a few incidents that caused the grandstand crowds at the starting and finishing line to sit up and take notice.

There were only a few occasions when cars came down the stretch in close proximity and therefore the race was not a pronounced success from the spectacular point of view. Once the Fiat and the Simplex came tearing along within a few yards of each other, making a pretty race, and toward the late afternoon the three cars left in the race after Strang had finished, fol-

lowed at distances of something like a few hundred yards apart. At another time Strang and Burman gave the people at the hairpin turn a scare as the two cars came whirling along with Strang almost on top of the other. The road liners fell back and Burman's mechanic looked anxious, but Strang laughed and the instant he had the room to pass, scurried by in a cloud of dust.

An unusual incident occurred at the grandstand when Grant in the American Locomotive car came whirling along at the finish of one lap. The left front tire rolled off and indulged in an impromptu race. Grant had power in his car while the tire had only impetus to carry it along and it lost out, while Grant continued some miles before he put on another tire.
